HERMITE-PADÉ APPROXIMANTS FOR A PAIR OF CAUCHY TRANSFORMS WITH OVERLAPPING SYMMETRIC SUPPORTS

ALEXANDER I. APTEKAREV, WALTER VAN ASSCHE, AND MAXIM L. YATTSELEV

Abstract. Hermite-Padé approximants of type II are vectors of rational functions with common denominator that interpolate a given vector of power series at infinity with maximal order. We are interested in the situation when the approximated vector is given by a pair of Cauchy transforms of smooth complex measures supported on the real line. The convergence properties of the approximants are rather well understood when the supports consist of two disjoint intervals (Angelesco systems) or two intervals that coincide under the condition that the ratio of the measures is a restriction of the Cauchy transform of a third measure (Nikishin systems). In this work we consider the case where the supports form two overlapping intervals (in a symmetric way) and the ratio of the measures extends to a holomorphic function in a region that depends on the size of the overlap. We derive Szegő-type formulae for the asymptotics of the approximants, identify the convergence and divergence domains (the divergence domains appear for Angelesco systems but are not present for Nikishin systems), and show the presence of overinterpolation (a feature peculiar for Nikishin systems but not for Angelesco systems). Our analysis is based on a Riemann-Hilbert problem for multiple orthogonal polynomials (the common denominator).

1 INTRODUCTION

For $p \in \mathbb{N}$, let $\vec{f} = (f_1, \dots, f_p)$ be a vector of holomorphic germs at infinity. Given a multi-index $\vec{n} = (n_1, \dots, n_p) \in \mathbb{N}^p$, the *type II Hermite-Padé approximant* to $\vec{f}$ corresponding to $\vec{n}$,

$$\vec{\pi}_{\vec{n}} = \left(\pi_{\vec{n}}^{(1)}, \dots, \pi_{\vec{n}}^{(p)}\right), \quad \pi_{\vec{n}}^{(i)} := \frac{P_{\vec{n}}^{(i)}}{Q_{\vec{n}}}, \tag{1.1}$$

is a vector of rational functions with common denominator $Q_{\vec{n}}$ satisfying

$$\begin{cases} \deg(Q_{\vec{n}}) \leqslant |\vec{n}| = n_1 + \cdots + n_p \\ R_{\vec{n}}^{(i)}(z) := \left(Q_{\vec{n}} f_i - P_{\vec{n}}^{(i)}\right)(z) = \mathcal{O}\left(z^{-n_i - 1}\right) \quad \text{as} \quad z \to \infty \end{cases} \tag{1.2}$$

for each $i \in \{1, \dots, p\}$. We shall not deal with type I Hermite-Padé approximants in this work and therefore henceforth we will drop the "type II" modifier. Such approximants were introduced by Hermite [23] for the vector of exponentials $(1, e^z, \dots, e^{(p-1)z})$, with the interpolation taking place at the origin rather than at infinity, as a tool in proving the transcendence of e. Later, his student Padé systematically studied the scalar case $p = 1$ [30] and such approximants are now called *Padé approximants*.

From our perspective interpolating at infinity is more convenient than interpolating at the origin in the following sense. Any holomorphic function can be written as a Cauchy integral of its boundary values on any curve encircling a domain of analyticity. For a holomorphic function on a domain we will use the terminology *trace* to mean the boundary values of the function on the boundary of the domain. When the function is holomorphic at infinity, such an integral representation can in some important cases be deformed analytically into an integral over a "one dimensional" set. A particular fruitful example of this principle is when we deal with Markov functions. Let μ_i be a positive measure and take

$$f_i(z) = \int \frac{d\mu_i(x)}{x-z}, \qquad \mathrm{supp}(\mu_i) \subseteq [a_i, b_i] \subset \mathbb{R}. \tag{1.3}$$

The vector $\vec{f}$ is called an *Angelesco system* if $[a_j, b_j] \cap [a_i, b_i] = \varnothing$ for $j \neq i$ (such systems were initially considered by Angelesco [1] and later rediscovered by Nikishin [27]). Angelesco has shown that $Q_{\vec{n}}$ has exactly n_i zeros on $[a_i, b_i]$. This means that an Angelesco system is an example of a *perfect* system, i.e., a system for which every multi-index is *normal*, that is, $\deg(Q_{\vec{n}}) = |\vec{n}|$. As far as the asymptotic behavior of $\pi_{\vec{n}}^{(j)}$ is concerned, convergence properties are not as straightforward as one could hope. Given an Angelesco system and a sequence of multi-indices such that $n_i/|\vec{n}| \to c_i > 0$, $c_1 + \cdots + c_p = 1$, Gonchar and Rakhmanov [21] have shown that for each j the complement of $\cup_{i=1}^p [a_i, b_i]$ is separated by a system of analytic arcs into two domains, say D_j^+, containing the point at infinity, and D_j^-, possible empty, such that $\pi_{\vec{n}}^{(j)}$ converges to f_j in D_j^+ and diverges to infinity in D_j^-. Moreover, the polynomials $Q_{\vec{n}}$ can have an asymptotic zero distribution (in the sense of weak* convergence) on a strict subset of $\cup_{i=1}^p \mathrm{supp}(\mu_i)$ (*pushing effect*). The pushing effect always implies existence of a divergence region but the reverse implication is not true. More detailed (strong) asymptotics for Hermite-Padé approximants to Angelesco systems when $p = 2$ and the weights $d\mu_i/dx$ satisfy the so-called *Szegő condition*, was obtained by the first author in [2].

Another class of Markov functions for which positive convergence results were obtained is now known as *Nikishin systems* [28]. The functions f_i in (1.3) form a Nikishin system if they all are supported on the same interval $[a, b]$ and the Radon-Nikodym derivatives $d\mu_j/d\mu_1$, $j \in \{2, \dots, p\}$, form a Nikishin system of order $p-1$ with respect to some interval $[c, d]$ such that $[c, d] \cap [a, b] = \varnothing$. Nikishin himself [28] has shown that such systems are perfect when $p = 2$ and the Hermite-Padé approximants converge uniformly outside of the interval $[a, b]$ in this case. This puts Nikishin systems more in line with the Padé case $p = 1$ (Markov theorem [26]) as neither the pushing effect nor the possibility of non-empty divergence regions appears for them. However, Nikishin systems do possess one new phenomenon, namely overinterpolation. It turns out that $R_{\vec{n}}^{(2)}$ has zeros on $[c, d]$ that are dense on this interval. It took 30 years to prove that Nikishin systems are perfect for any p [17]. In [17], Fidalgo Prieto and López Lagomasino also proved uniform convergence for multi-indices close to the diagonal. Strong asymptotics in the case of diagonal multi-indices and Szegő weights was derived by the first author in [3].

It is interesting to observe that the first result on strong asymptotics of Hermite-Padé approximants was obtained by Kalaygin [24] for the case of two touching symmetric intervals (the limiting case of an Angelesco system).

As often happens in mathematics, the treatment of Angelesco and Nikishin systems can be unified under the umbrella of *generalized Nikishin systems* (GN-systems) as introduced in [22], where Gonchar, Rakhmanov, and Sorokin defined a system of Markov functions with the help of a rooted tree graph and considered the question of uniform convergence of Hermite-Padé approximants to such a system. In such a set-up, an Angelesco system corresponds to a tree where the root is connected by p edges to p leaves and a Nikishin system corresponds to a tree in which every node except for the final leaf has exactly one child. Strong asymptotics of Hermite-Padé approximants to GN-systems of Markov functions generated by more general (than rooted tree) graphs (admitting cycles) was derived by the first author and Lysov in [8]. An example of GN-system from [8] is a pair of two Markov functions in (1.3) where the support of one of them is strictly included in the support of the other, i.e., $\mathrm{supp}(\mu_2) = [a_2, b_2] \subset \mathrm{supp}(\mu_1) = [a_1, b_1]$ and the Radon-Nikodym derivative $d\mu_2/d\mu_1$ along $[a_1, b_1]$ is a Markov function with support $[a_3, b_3]$ where $[a_3, b_3] \cap [a_1, b_1] = \varnothing$. Weak asymptotics of Hermite-Padé approximants to this example of Markov functions was derived by Rakhmanov in [32].

We emphasize that in all the results we listed above the *geometry* of the problem is *real*, i.e., the supports of the limiting distributions of the poles of the approximants and the overinterpolation points belong to $\mathbb{R}$.

In this paper we consider Hermite-Padé approximants to a pair of Cauchy transforms (Markov functions) of generally speaking complex measures with overlapping supports and aim at strong asymptotics. The set up does not fall into the framework of GN-systems, even when the measures are positive, as their supports overlap (for GN-systems the supports are either disjoint or one coincides with or contains the other). It turns out that both phenomena, the pushing effect and overinterpolation, appear in this case. Hermite-Padé approximants to a pair of Markov functions with overlapping supports were first considered by Stahl with the goal of proving weak asymptotics [34, 33, 9]. He had the important insight that the geometry of this problem is complex, i.e., the overinterpolation points are distributed on analytic arcs in the complex plane (later, a similar effect was observed in [5]). This discovery was very unusual at the time because the input geometry (i.e., the supports of the measures generating the Markov functions) is completely real. Unfortunately, Stahl's results have never been published. This work was strongly motivated by the desire to provide a detailed proof of his findings (in an even more delicate setting of strong asymptotics).

Opting here for complex measures is natural from the point of view of complex analysis. However, many techniques, like those in [2, 3], do not apply as they use positivity in an essential way. An approach that does not rely on positivity was outlined by Nuttall in his seminal paper [29]. There Nuttall conjectured that the main term of the asymptotics of Hermite-Padé approximants is a function solving of a certain *explicit* boundary value problem on some *unknown* Riemann surface. He identified this surface only in a handful of special cases. Elaborating on Nuttall's approach, the first two authors and Kuijlaars [7] pinpointed the algebraic equation which defines the appropriate Riemann surface in the case of two Cauchy transforms of complex measures supported on two arcs joining pairs of branch points in the complex plane (the simplest example is a complexified Angelesco system) and derived formulae of strong asymptotics in the case when the Riemann surface has genus zero. Below, we build upon the ideas developed in [7] and extend the results of [7] to the cases when the appropriated Riemann surface has positive genus (elliptic and ultra- elliptic case).

In Section 2 we identify the Riemann surface in Nuttall's program by an algebraic equation, discuss its realization as a ramified cover of $\overline{\mathbb{C}}$, and construct a certain function on this surface whose level lines will geometrically describe convergence and divergence domains of the approximants. In Section 3, we construct the Nuttall-Szegő functions that will provide the leading term of the asymptotics of the Hermite-Padé approximants. Finally, in Section 4 we state the main result of this work. The remaining part of the paper is devoted to the proofs of all the stated results.

2 RIEMANN SURFACE

Let $a \in (0,1)$ be given. Our goal is to investigate Hermite-Padé approximants to a pair of Markov-type functions generated by measures with supports $[-1,a]$ and $[-a,1]$. To this end we consider the algebraic equation

$$A(z)h^3 - 3B_2(z)h - 2B_1(z) = 0, \tag{2.1}$$

where the polynomials $A(z)$, $B_2(z)$, and $B_1(z)$ are defined by

$$\begin{cases} A(z) & := & (z^2-1)(z^2-a^2), \\ B_2(z) & := & z^2-p^2, \\ B_1(z) & := & z, \end{cases}$$

for some parameter $p > 0$. Denote by h_k, $k \in \{0,1,2\}$, the three distinct branches of the algebraic function h determined by (2.1). Naturally, these branches satisfy

$$\begin{cases} h_0 + h_1 + h_2 \equiv 0, \\ h_0h_1 + h_0h_2 + h_1h_2 = -3B_2/A, \\ h_0h_1h_2 = 2B_1/A. \end{cases} \tag{2.2}$$

Hence, it necessarily holds that $h_k(\infty) = 0$ and therefore $h_k(z) = c_k/z + \cdots$ as $z \to \infty$. It readily follows from the above equations that the constants c_k are the solutions of $0 = c^3 - 3c - 2 = (c+1)^2(c-2)$. Thus, we put

$$\begin{cases} h_0(z) &= \dfrac{2}{z} + \cdots \\ h_i(z) &= -\dfrac{1}{z} + \cdots \end{cases} \quad \text{as} \quad z \to \infty \tag{2.3}$$

for $i \in \{1,2\}$. It can easily be checked that all three solutions of (2.1) are real for positive large x. Hence, we can label the branches so that for all $x > 0$ large enough

$$h_0(x) > h_1(x) > h_2(x). \tag{2.4}$$

Denote by $\mathfrak{R}$ the Riemann surface of h. It is a three-sheeted ramified cover of $\overline{\mathbb{C}}$. We shall denote by $\mathfrak{R}^{(k)}$, $k \in \{0,1,2\}$, the sheet on which h coincides with h_k (a particular realization of this surface is specified in Theorem 1 below). We denote by $\boldsymbol{z}$ a generic point on $\mathfrak{R}$ with *natural projection* $\pi(\boldsymbol{z}) = z \in \overline{\mathbb{C}}$. If we want to specify the sheet, we write $z^{(k)}$ for $z^{(k)} \in \mathfrak{R}^{(k)}$ so that $\pi(z^{(k)}) = z$. Thus, $h_k(z) = h(z^{(k)})$. Consider the differential

$$d\mathcal{N}(\boldsymbol{z}) := h(\boldsymbol{z})d\boldsymbol{z}, \tag{2.5}$$

where $\boldsymbol{z}$ is a generic point on $\mathfrak{R}$. The choice of the parameter p is driven by the following condition:

$$N(\boldsymbol{z}) := \mathrm{Re}\left(\int^{\boldsymbol{z}} d\mathcal{N}\right) \quad \text{is a well defined (\textit{single-valued}) harmonic function on } \mathfrak{R}. \tag{2.6}$$

When it exists, $N(\boldsymbol{z})$ is defined up to an additive constant. If we denote by N_k the restriction of N to $\mathfrak{R}^{(k)}$, then it is easy to see that $N_1 + N_2 + N_3$ is a well defined harmonic function in $\overline{\mathbb{C}}$ and therefore it is constant. Thus, we normalize N so that

$$N_1(z) + N_2(z) + N_3(z) \equiv 0, \quad z \in \overline{\mathbb{C}}. \tag{2.7}$$

Notice also that (2.6) is equivalent to requiring that all the periods of the differential $d\mathcal{N}$ are purely imaginary.

Theorem 1. *Consider the algebraic equation (2.1) with $a \in (0,1)$.*

(I) *If $a \in \left(0, 1/\sqrt{2}\right)$, then there exists $p \in \left(a, \sqrt{(1+a^2)/3}\right)$ such that condition (2.6) is fulfilled. In this case $\mathfrak{R}$ has eight ramification points whose projections are $\{\pm1, \pm a\}$ and $\{\pm b, \pm ic\}$ for some uniquely determined $b \in (a,p)$ and $c > 0$. Moreover, the surface can be realized as on Figure 1(a);*

(II) *If $a = 1/\sqrt{2}$, then condition (2.6) is fulfilled for $p = 1/\sqrt{2}$. In this case $\mathfrak{R}$ has four ramification points whose projections are $\left\{\pm1, \pm1/\sqrt{2}\right\}$ and it can be realized as on Figure 1(b);*

(III) *If $a \in \left(1/\sqrt{2}, 1\right)$, then condition (2.6) is fulfilled for for $p = \sqrt{(1+a^2)/3}$. In this case $\mathfrak{R}$ has six ramification points whose projections are $\{\pm1, \pm a\}$ and $\{\pm b\}$ for some uniquely determined $b \in (p,a)$. Moreover, the surface can be realized as on Figure 1(c).*

The points b and c in Case I and the point b in Case III can be explicitly computed as they are solutions of a certain explicit quadratic or linear (in z^2) equation whose parameters depend on a and p.

It follows from Theorem 1 that $\mathfrak{R}$ has genus $g = 2$ when $a \in \left(0, 1/\sqrt{2}\right)$ and genus $g = 1$ otherwise. Moreover, in Cases I and III, all the ramification points have order 2 while in Case II the points ±1 have order 2 while $\pm1/\sqrt{2}$ have order 3.

FIGURE 1. Ramification points of $\mathfrak{R}$ and the cuts (black curves) along which the sheets $\mathfrak{R}^{(0)}, \mathfrak{R}^{(1)}, \mathfrak{R}^{(2)}$ are glued to each other.

In the light of Theorem 1, it will be convenient to fix the following notation:

$$\left\{\begin{array}{lll} \Delta_0 & := & \pi\big(\text{cycle that separates } \mathfrak{R}^{(1)} \text{ and } \mathfrak{R}^{(2)}\big), \\ \Delta_1 & := & \pi\big(\text{cycle that separates } \mathfrak{R}^{(0)} \text{ and } \mathfrak{R}^{(1)}\big), \\ \Delta_2 & := & \Delta_{21} \cup \Delta_{22}, \\ \Delta_{21} & := & \pi\big(\text{the left cycle of the chain that separates } \mathfrak{R}^{(0)} \text{ and } \mathfrak{R}^{(2)}\big), \\ \Delta_{22} & := & \pi\big(\text{the right cycle of the chain that separates } \mathfrak{R}^{(0)} \text{ and } \mathfrak{R}^{(2)}\big). \end{array}\right. \tag{2.8}$$

Clearly, Δ_0 is defined only in Case I.

Let $d\mathcal{N}$ be defined by (2.5). The function

$$\Phi(z) := \exp\left\{\int^z d\mathcal{N}\right\} \tag{2.9}$$

is analytic, except for a double pole at $\infty^{(0)}$, and multiplicatively multi-valued on $\mathfrak{R}$. Moreover, it is single-valued in $\mathfrak{R}_{\alpha,\beta} := \mathfrak{R} \setminus \bigcup_{i=1}^{g}(\alpha_i \cup \beta_i)$, where $\{\alpha_i, \beta_i\}_{i=1}^{g}$ is a homology basis on $\mathfrak{R}$. Later on, see Figure 2, we shall specify the basis in more detail, but right now it is sufficient to assume that each cycle $\gamma \in \{\alpha_i, \beta_i\}_{i=1}^{g}$ possesses a *projective involution*: $|\gamma \cap \pi^{-1}(z)| = 2$ for any $z \in \pi(\gamma)$ which is not a branch point of $\mathfrak{R}$ (the involution is then defined by mapping a point on γ to the other one with the same projection). We normalize Φ so that

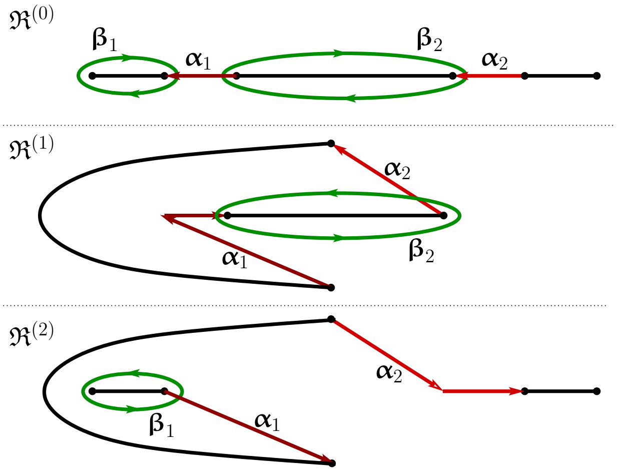
$$\Phi^{(0)}\Phi^{(1)}\Phi^{(2)} \equiv 1 \quad \text{in} \quad \overline{\mathbb{C}}, \tag{2.10}$$

where $\Phi^{(k)}$ is the pullback to $\mathbb{C}$ of the restriction of Φ to $\mathfrak{R}^{(k)}$. Let us show that such a normalization is indeed possible. Since $\mathfrak{R}_{\alpha,\beta}$ is simply connected and $d\mathcal{N}$ has integer residues, the restriction of Φ to $\mathfrak{R}_{\alpha,\beta}$ is single-valued. It satisfies

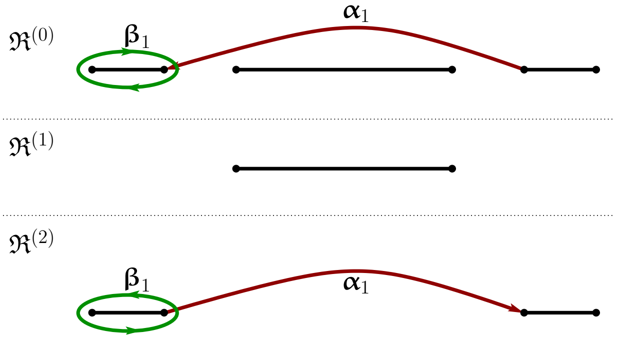
$$\Phi^+ = \Phi^- \left\{\begin{array}{lll} \exp\{2\pi i \omega_i\} & \text{on} & \alpha_i, \\ \exp\{2\pi i \tau_i\} & \text{on} & \beta_i, \end{array}\right. \tag{2.11}$$

$1 \leqslant i \leqslant g$, where the constants ω_i and τ_i are real (this is guaranteed by (2.6)) and given by

$$\omega_i := -\frac{1}{2\pi i}\oint_{\beta_i} d\mathcal{N}, \qquad \tau_i := \frac{1}{2\pi i}\oint_{\alpha_i} d\mathcal{N}. \tag{2.12}$$



(a) Case I



(b) Cases II and III (there is no gap between the cuts on $\mathfrak{R}^{(0)}$ in Case II, but this does not affect the choice of the cycles)

FIGURE 2. Homology basis for $\mathfrak{R}$.

At times, it will be convenient to use vector notation $\vec{\tau} = (\tau_1, \tau_2)^\mathsf{T}$ and $\vec{\omega} = (\omega_1, \omega_2)^\mathsf{T}$ if $g = 2$ and $\vec{\tau} = (\tau_1)$ and $\vec{\omega} = (\omega_1)$ if $g = 1$. Since Φ has a double pole at $\infty^{(0)}$ and simple zeros at $\infty^{(1)}, \infty^{(2)}$, we can write

$$\left\{ \begin{array}{lll} \Phi^{(0)}(z) & = & C_0 z^2 + \cdots \\ \Phi^{(i)}(z) & = & C_i z^{-1} + \cdots \end{array} \right. \quad \text{as} \quad z \to \infty. \tag{2.13}$$

It follows from (2.7) that $\log|\Phi^{(0)}\Phi^{(1)}\Phi^{(2)}| \equiv 0$ on $\overline{\mathbb{C}}$. Hence, if we choose the normalization $C_0C_1C_2 = 1$, then (2.10) is fulfilled due to our choice of the homology basis: since the cycles possess projective involutions, exactly two pullbacks of Φ have jumps at each point belonging to the projection of a homology cycle, moreover, the jumps are reciprocal as the projected parts of the cycle coincide as sets but have opposite orientations.

Due to the symmetries of the Riemann surface, the vectors $\vec{\omega}$ and $\vec{\tau}$ take special forms. To be more specific, let us fix a homology basis. We choose $\pi(\beta_1) = \Delta_{21}$ and, in Case I, $\pi(\beta_2) = \Delta_1$, see (2.8), while the $\boldsymbol{\alpha}$-cycles are as on Figure 2(a) in Case I and the $\boldsymbol{\alpha}_1$-cycle should be chosen as on Figure 2(b) in Cases II and III.

Proposition 2. *Let $\{\boldsymbol{\alpha}_i, \boldsymbol{\beta}_i\}_{i=1}^{g}$ be the homology basis which we just fixed. In Case I, one has*

$$\vec{\omega} = \big(\omega, 2(1-\omega)\big)^\mathsf{T} \quad \textit{and} \quad \vec{\tau} = \big(\tau, -\tau\big)^\mathsf{T} \tag{2.14}$$

for some real constants $\tau = \tau(a)$ and $\omega = \omega(a) \in (1/2, 1)$. In Cases II and III, one has

$$\vec{\omega} = \vec{\tau} = (1/2). \tag{2.15}$$

Recall that $|\Phi(z)| = \exp\{N(z)\}$ is a single-valued function on $\mathfrak{R}$, see (2.7). The asymptotics of the Hermite-Padé approximants will depend on the relative sizes of the different branches of $|\Phi|$ (in other words, on the size of the branches of N). To this end, define Ω_{ijk} to be open subset of $\overline{\mathbb{C}}$ such that

$$\Omega_{ijk} := \left\{ z : \left|\Phi^{(i)}(z)\right| > \left|\Phi^{(j)}(z)\right| > \left|\Phi^{(k)}(z)\right| \right\}.$$

We also define the closed set $\Gamma := \Gamma_{01} \cup \Gamma_{02} \cup \Gamma_{12}$ by

$$\Gamma_{ij} := \left\{ z : \left|\Phi^{(i)}(z)\right| = \left|\Phi^{(j)}(z)\right|,\ i \neq j \right\}.$$

Clearly, $\overline{\mathbb{C}} \setminus \Gamma = \bigcup_{i \neq j \neq k \neq i} \Omega_{ijk}$. Then the following theorem holds.

Theorem 3. *In Case I, the regions Ω_{ijk} are distributed as on Figure 3(a); in Case II, the domains are distributed as on Figure 3(b); in Case III, the domains are distributed as on Figure 3(c,d).*

We prove Theorems 1 and 3 as well as Proposition 2 in Section 6.

3 NUTTALL-SZEGŐ FUNCTIONS

To define the Nuttall-Szegő functions, we first need to formulate a certain *Jacobi inversion problem*. To this end, denote by

$$\vec{\Omega}(z) = \left(\Omega_1(z), \dots, \Omega_g(z)\right)^{\mathsf{T}}$$

the vector of g normalized holomorphic integrals on $\mathfrak{R}$. That is, $\vec{\Omega}(z)$ is a vector of analytic and additively multi-valued functions on $\mathfrak{R}$ that are single-valued on $\mathfrak{R}_{\alpha,\beta}$ and satisfy

$$\vec{\Omega}^{+} - \vec{\Omega}^{-} = \left\{ \begin{array}{lll} -\mathbf{B}\vec{e}_i & \text{on} & \alpha_i, \\ \vec{e}_i & \text{on} & \beta_i, \end{array} \right. \qquad \mathbf{B} := \left[\oint_{\beta_j} d\Omega_i \right]_{j,i=1}^{g}, \tag{3.1}$$

where $\vec{e}_i$ is the i-th vector of the standard basis in $\mathbb{R}^g$. It is known that $\mathbf{B}$ is a symmetric matrix with positive definite imaginary part when $g = 2$ and is a complex number with $\operatorname{Im}(\mathbf{B}) > 0$ when $g = 1$. The Jacobi inversion problem we need consists of finding an integral divisor[1] of order g, say $\mathcal{D}_n$, such that

$$\vec{\Omega}(\mathcal{D}_n) \equiv \vec{\Omega}(g\infty^{(2)}) + \vec{c}_\rho + n(\vec{\omega} + \mathbf{B}\vec{\tau}) \quad (\text{mod periods } d\vec{\Omega}), \tag{3.2}$$

where $\vec{c}_\rho$ is a vector of constants that depends only on the approximated functions and is defined further below in (7.11), $\vec{\tau}$ and $\vec{\omega}$ are the vectors defined after (2.12), and the equivalence of two vectors $\vec{c}, \vec{e} \in \mathbb{C}^g$ is defined by

$$\vec{c} \equiv \vec{e} \quad \left(\text{mod periods } d\vec{\Omega}\right) \quad \Leftrightarrow \quad \vec{c} - \vec{e} = \vec{j} + \mathbf{B}\vec{m}, \qquad \vec{j}, \vec{m} \in \mathbb{Z}^g. \tag{3.3}$$

It is known that the Jacobi inversion problem has a unique solution when $g = 1$. Hence, $\mathcal{D}_n$ is well defined for all n in this case. Moreover, the following proposition holds.

Proposition 4. *Assuming* $g = 1$, *let* $\mathcal{D}_n$ *be the unique solution of* (3.2). *Then* $\mathcal{D}_{2m} = \mathcal{D}_0$ *and* $\mathcal{D}_{2m+1} = \mathcal{D}_1$ *for all* $m \geqslant 0$. *Moreover, either* $\mathcal{D}_0 \neq \infty^{(0)}$ *or* $\mathcal{D}_1 \neq \infty^{(0)}$ *and therefore* $\mathbb{N}_* := \left\{ n \in \mathbb{N} : \mathcal{D}_n \neq \infty^{(0)} \right\}$ *is infinite.*

The unique solvability of a Jacobi inversion problem is no longer guaranteed when $g = 2$. However, it is known that solutions are either unique or given by any *special divisor*[2]. Notice that integral divisors of order 2 can be considered as elements of $\mathfrak{R}^2/\Sigma_2$, where Σ_2 is the symmetric group of two elements. This is a compact topological space. Hence, we can talk about limit points of sequences of integral divisors.

Proposition 5. *Let* $g = 2$, *then* (3.2) *has a unique solution for at least one of the indices* $n-1, n$ *for any* $n \in \mathbb{N}$. *Moreover, there always exists an infinite subsequence* $\mathbb{N}_*$ *such that no limit point of* $\left\{ \mathcal{D}_n \right\}_{n \in \mathbb{N}_*}$ *is a special divisor or is of the form* $\infty^{(0)} + \boldsymbol{w}$ *for some* $\boldsymbol{w} \in \mathfrak{R}$.

The following theorem is the main result of this section.

Theorem 6. *Let* ρ_1 *and* ρ_2 *be functions holomorphic and non-vanishing in a neighborhood of* $[-1, 1]$. *In Case I, assume in addition that the ratio* ρ_2/ρ_1 *holomorphically extends to a non-vanishing function in a neighborhood of* Δ_0. *Denote by* $\boldsymbol{\Delta}$ *the chain that separates* $\mathfrak{R}^{(0)}$, $\mathfrak{R}^{(1)}$, *and* $\mathfrak{R}^{(2)}$ ($\pi(\boldsymbol{\Delta})$ *is a union of sets defined in* (2.8)). *For each* n *for which* (3.2) *is uniquely solvable, there exists a function, say* Ψ_n, *meromorphic in* $\mathfrak{R} \setminus \boldsymbol{\Delta}$ *such that the zero/pole multi-set of* Ψ_n *is given by*

$$\mathcal{D}_n + (n+1)\left(\infty^{(1)} + \infty^{(2)}\right) - 2n\infty^{(0)}. \tag{3.4}$$

Its traces are bounded except at the branch points of $\mathfrak{R}$ *where* Ψ_n *behaves like*

$$\left|\Psi_n(z)\right| \sim |z - e|^{-1/4} \quad \text{as} \quad z \to e, \tag{3.5}$$

---

[1] Recall that an *integral divisor* of order d is a formal expression $\mathcal{D} = \sum_i n_i z_i$, where $n_i \in \mathbb{N}$ and $\sum_i n_i = d$. A *principal divisor* is an expression $\sum_{i=1}^{k} n_i \boldsymbol{t}_i - \sum_{i=1}^{j} m_i \boldsymbol{w}_i$ such that there exists a rational function on $\mathfrak{R}$ with a zero of multiplicity n_i at $\boldsymbol{t}_i$ for each $i \in \{1, \ldots, k\}$, a pole of order m_i at $\boldsymbol{w}_i$ for each $i \in \{1, \ldots, j\}$, and is otherwise non-vanishing and finite (in particular, one has that $\sum_{i=1}^{k} n_i = \sum_{i=1}^{j} m_i$).

[2] On genus 2 surfaces, a *special divisor* is an integral divisor of order 2 such that there exists a rational function on $\mathfrak{R}$ with simple poles at the elements of the divisor (a double pole if they coincide) and otherwise regular.

for every branch point $\mathbf{e}$ *of* $\mathfrak{R}$ *except when* $\mathbf{e} = \pm 1/\sqrt{2}$ *(Case II only) where the exponent* $-1/4$ *should be replaced by* $-1/3$*. Furthermore*

$$\begin{cases} \left(\Psi_n^{(1)}\right)^{\pm} & = \pm\left(\Psi_n^{(0)}\right)^{\mp}\rho_1 & \text{on} \quad \Delta_1^{\circ}, \\ \left(\Psi_n^{(2)}\right)^{\pm} & = \mp\left(\Psi_n^{(0)}\right)^{\mp}\rho_2 & \text{on} \quad \Delta_{21}^{\circ}, \\ \left(\Psi_n^{(2)}\right)^{\pm} & = \pm\left(\Psi_n^{(0)}\right)^{\mp}\rho_2 & \text{on} \quad \Delta_{22}^{\circ}, \\ \left(\Psi_n^{(2)}\right)^{\pm} & = \pm\left(\Psi_n^{(1)}\right)^{\mp}(\rho_2/\rho_1) & \text{on} \quad \Delta_0^{\circ}, \end{cases} \tag{3.6}$$

where Δ° *is the interior of the arc* Δ*. Moreover, if* Ψ *is a function meromorphic in* $\mathfrak{R}\setminus\boldsymbol{\Delta}$ *satisfying* (3.6)*,* (3.5)*, and* (3.4) *with* $\mathcal{D}_n$ *replaced by any other integral divisor* $\mathcal{D}$*, then* Ψ *is a constant multiple of* Ψ_n*.*

It might seem, especially after looking at (3.2), that the construction of the Nuttall-Szegő functions Ψ_n, particularly, the divisors $\mathcal{D}_n$, depends on the choice of the homology basis. However, this is precisely the point of the uniqueness part of Theorem 6 that the functions Ψ_n are independent of the intermediate steps of their construction.

The Nuttall-Szegő functions Ψ_n are certain multiples of the functions Φ^n. In fact, their ratios form a normal family on each $\mathfrak{R}_\varepsilon$ obtained from $\mathfrak{R}$ by excising circular neighborhoods of radius ε around the branch points.

Theorem 7. *Let* $\mathbb{N}_* \subseteq \mathbb{N}$ *be a subsequence as in Propositions 4 or 5. For each* $\varepsilon > 0$*, there exists a constant* $C_\varepsilon(\mathbb{N}_*) > 1$ *such that*

$$\begin{cases} |\Psi_n| \leqslant C_\varepsilon(\mathbb{N}_*)\,|\Phi^n| & \text{in} \quad \mathfrak{R}_\varepsilon, \\ |\Psi_n| \geqslant C_\varepsilon(\mathbb{N}_*)^{-1}\,|\Phi^n| & \text{in} \quad \mathfrak{R}^{(0)} \cap \pi^{-1}\big\{|z| > 1/\varepsilon\big\}. \end{cases} \tag{3.7}$$

We prove Propositions 4 and 5 as well as Theorems 6 and 7 in Section 7.

4 ASYMPTOTICS OF HERMITE-PADÉ APPROXIMANTS

Below, we consider vector functions $\vec{f} := (f_1, f_2)$ of the form

$$f_j(z) := \frac{1}{2\pi i}\int_{F_j}\frac{\rho_j(x)}{x-z}\,dx, \quad j \in \{1,2\}, \tag{4.1}$$

where $F_1 = [-1, a]$ and $F_2 = [-a, 1]$, $a \in (0,1)$, and ρ_j are holomorphic and non-vanishing in a neighborhood of $[-1,1]$. Additionally, we impose the following condition on the functions ρ_j:

Condition 8. *The ratio* ρ_2/ρ_1 *extends from* $(-a, a)$ *to a holomorphic and non-vanishing function*

- *in a domain that contains in its interior the closure of all the bounded components of the regions* Ω_{ijk} *in Case I, see Figure 3(a);*
- *in a domain whose complement is compact and belongs to the right-hand component of* Ω_{021} *in Cases II and IIIa, see Figures 3(b,c);*
- *in the extended complex plane, i.e., the ratio is a non-zero constant, in Case IIIb.*

Condition 8 needs to be regarded in the following context. As conjectured in [4] and supported by the results for Nikishin systems, given $\vec{f}$ of the form (4.1), the appropriate Riemann surface $\mathfrak{R}$ must depend on the analytic continuation of ρ_2/ρ_1 from $F_1 \cap F_2$. In this work, on the other hand, we fixed the surface by considering (2.1), which necessitates a condition on the continuation of ρ_2/ρ_1 of the above type.

In what follows, we assume that $a \in (0,1)$ is fixed and the vector $\vec{f} = (f_1, f_2)$ is given by (4.1), where ρ_1 and ρ_2 satisfy Condition 8; Ψ_n are the Nuttall-Szegő functions of

Theorem 6 corresponding to a and the functions ρ_1 and ρ_2, constructed on the Riemann surface $\mathfrak{R}$ of h realized as in Theorem 1; the constants C_n are defined by

$$C_n^{-1} := \lim_{z\to\infty} \Psi_n^{(0)}(z)z^{-2n}; \tag{4.2}$$

$Q_{\vec n}$ are the monic denominators of the Hermite-Padé approximants $\vec\pi_{\vec n}$ to $\vec f$, which are also multiple orthogonal polynomials with respect to the weights ρ_1 and ρ_2, see (5.1)), and $R_{\vec n}^{(i)}$, $i \in \{1,2\}$, are the linearized errors of approximation corresponding to the multi-indices $\vec n = (n,n)$, $n \in \mathbb{N}$, see (1.1)–(1.2).

To describe the asymptotics of $R_{\vec n}^{(i)}$, it will be convenient to put

$$\left\{\begin{array}{lcl} \Gamma_1 & := & \Gamma_{12}^- \setminus \Delta_0, \\ \Gamma_2 & := & \Gamma_{12}^+, \end{array}\right. \quad \text{and} \quad \left\{\begin{array}{lcl} \Omega_1 & := & \left(\overline{\Omega}_{021}^- \cup \overline{\Omega}_{201}^-\right) \setminus \left(\Gamma_{12} \cup \Delta_1 \cup \Delta_2\right), \\ \Omega_2 & := & \left(\overline{\Omega}_{021}^+ \cup \overline{\Omega}_{201}^+ \cup \overline{\Omega}\right) \setminus \left(\Gamma_{12}^+ \cup \Delta_1 \cup \Delta_2\right), \end{array}\right.$$

where Δ_1 and Δ_2 were introduced in (2.8), $\Gamma_{12}^\pm := \Gamma_{12} \cap \{\pm\mathrm{Re}(z) > 0\}$, $\Omega_{ijk}^\pm := \Omega_{ijk} \cap \{\pm\mathrm{Re}(z) > 0\}$, and Ω is present only in Case I and is equal to the unbounded component of Ω_{012}^-, see Figures 4 and 3. Observe that $\Omega_1 = \Omega_2 = \varnothing$ in Case IIIb. Define

$$\widehat\Psi_n^{(1)} := \left\{\begin{array}{ll} -\frac{\rho_1}{\rho_2}\Psi_n^{(2)} & \text{in } \Omega_1, \\ \Psi_n^{(1)} & \text{otherwise}, \end{array}\right. \quad \text{and} \quad \widehat\Psi_n^{(2)} := \left\{\begin{array}{ll} \Psi_n^{(2)} & \text{in } \Omega_2, \\ \frac{\rho_2}{\rho_1}\Psi_n^{(1)} & \text{otherwise}. \end{array}\right. \tag{4.3}$$

In Case I, it follows from (3.6) that $\widehat\Psi_n^{(i)}$ is the analytic continuation of $\Psi_n^{(i)}$ across Δ_0 until Γ_i, which always exists by the analyticity of ρ_i's. In Cases II and III it still holds by (3.6) that $\widehat\Psi_n^{(i)}$ is an analytic continuation of $\Psi_n^{(i)}$. However, this time one needs to continue $\Psi_n^{(1)}$ through $\Delta_1^\pm$ into $\mathfrak{R}^{(0)}$ and then through $\Delta_{21}^\mp$ into $\mathfrak{R}^{(2)}$ while $\Psi_n^{(2)}$ needs to be continued through $\Delta_{22}^\pm$ into $\mathfrak{R}^{(0)}$ and then through $\Delta_1^\mp$ into $\mathfrak{R}^{(1)}$.

For any $\delta > 0$, we further define

$$\mathcal{N}_\delta := \{z : \ |\mathrm{Im}(z)| < \delta, \ \mathrm{Re}(z) \in \Delta_1 \cup \Delta_2, \ \mathrm{dist}\,(\mathrm{Re}(z), \{\text{endpoints of } \Delta_1 \text{ and } \Delta_2\}) > \delta\},$$

and

$$\mathcal{N}_\delta^{(i)} := \left\{\begin{array}{ll} \{z = t + x : \ x \in (-\delta,\delta), \ t \in \Gamma_i, \ \delta < |\mathrm{Im}(t)| < c - \delta\} & \text{in Case I}, \\ \{z = t + x : \ x \in (-\delta,\delta), \ t \in \Gamma_i, \ \delta < |\mathrm{Im}(t)| < 1/\delta\} & \text{in Case II}, \\ \{z : \ \mathrm{dist}(z,\Gamma_i) < \delta, \ |\mathrm{Im}(z)| > \delta \text{ when } |\mathrm{Re}(z)| < 1\} & \text{in Case III}. \end{array}\right.$$

Finally, let us introduce the following notation. Given a sequence of functions F_n, a sequence of finite multi-sets X_n, and positive numbers ϵ_n, we write

$$F_n = \mathcal{O}\left(\epsilon_n; X_n\right) \quad \Leftrightarrow \quad F_n(z) \prod_{x \in X_n} \frac{|z - x|}{\sqrt{(1+|z|^2)(1+|x|^2)}} = \mathcal{O}(\epsilon_n).$$

Then the following theorem holds.

Theorem 9. *Let $\mathbb{N}_*$ be a subsequence from either Proposition 4 or Proposition 5 (depending on whether $a \geqslant 1/\sqrt{2}$ or $a < 1/\sqrt{2}$), and $i \in \{1,2\}$. Then*

$$\left\{\begin{array}{lcl} Q_{\vec n} & = & C_n \Psi_n^{(0)} \left(1 + \mathcal{O}(\epsilon_n; X_n)\right), \\ R_{\vec n}^{(i)} & = & C_n \widehat\Psi_n^{(i)} \left(1 + \mathcal{O}(\epsilon_n; X_n^{(i)})\right), \end{array}\right. \quad n \in \mathbb{N}_*, \tag{4.4}$$

locally uniformly in $\overline{\mathbb{C}} \setminus (\Delta_1 \cup \Delta_2)$ and $\overline{\mathbb{C}} \setminus (F_i \cup \Gamma_i)$, respectively, where X_n is the multi-set of zeros of $\Psi_n^{(0)}$ in $\overline{\mathbb{C}} \setminus (\Delta_1 \cup \Delta_2)$, $X_n^{(i)}$ is the multi-set of zeros of $\widehat\Psi_n^{(i)}$ in $\overline{\mathbb{C}} \setminus (F_i \cup \Gamma_i)$, and[3] $\epsilon_n \to 0$. Moreover, there exists $\delta_0 > 0$ such that for all $\delta \in (0,\delta_0)$ one has

$$\left\{\begin{array}{lcl} Q_{\vec n} & = & C_n \Psi_{n+}^{(0)} \left(1 + \mathcal{O}(\epsilon_n; X_{n+})\right) + C_n \Psi_{n-}^{(0)} \left(1 + \mathcal{O}(\epsilon_n; X_{n-})\right), \\ R_{\vec n}^{(i)} & = & C_n \widehat\Psi_{n+}^{(i)} \left(1 + \mathcal{O}\left(\epsilon_n; X_{n+}^{(i)}\right)\right) + C_n \widehat\Psi_{n-}^{(i)} \left(1 + \mathcal{O}\left(\epsilon_n; X_{n-}^{(i)}\right)\right), \end{array}\right. \quad n \in \mathbb{N}_*, \tag{4.5}$$

---

[3] In Cases I and III one has $\epsilon_n = n^{-1}$ and $\epsilon_n = n^{-1/6}$ in Case II.

(f) Case IIIa

FIGURE 4. The sets Γ_i (non-horizontal bold lines), the domains Ω_i (shaded regions), and the boundary of the domain of holomorphy of $\widehat{\Psi}_n^{(1)}$ (bold lines).

locally uniformly in $\mathcal{N}_\delta$ *and* $\mathcal{N}_\delta^{(i)}$*, respectively, where* $\Psi_{n\pm}^{(0)}$ *are functions holomorphic in* $\mathcal{N}_\delta$ *that coincide with* $\big(\Psi_n^{(0)}\big)^\pm$ *on* $\Delta_1^\circ \cup \Delta_2^\circ$ *and* $X_{n\pm}$ *are their multi-sets of zeros in* $\mathcal{N}_\delta$*, and* $\widehat{\Psi}_{n\pm}^{(i)}$ *are functions holomorphic in* $\mathcal{N}_\delta^{(i)} \setminus F_i$ *that coincide with* $\big(\widehat{\Psi}_n^{(i)}\big)^\pm$ *on* $\Gamma_i^\circ \setminus F_i$ *and* $X_{n\pm}^{(i)}$ *are their multi-sets of zeros in* $\mathcal{N}_\delta^{(i)}$.

It follows from Theorems 3 and 7 that in Cases I and III we observe the pushing effect, i.e, $a \neq b$, and the presence of divergence regions (both phenomena are observed in Angelesco systems). Indeed, according to (1.2) and (4.4), one has locally uniformly in $\overline{\mathbb{C}} \setminus \big([-1,1] \cup \Gamma_i\big)$ that

$$f_i - \pi_{\vec{n}}^{(i)} = \frac{\widehat{\Psi}_n^{(i)}}{\Psi_n^{(0)}} \frac{1 + \mathcal{O}\big(\epsilon_n; X_n^{(i)}\big)}{1 + \mathcal{O}\big(\epsilon_n; X_n\big)}.$$

Hence, the error of approximation $f_i - \pi_{\vec{n}}^{(i)}$ is geometrically small in $\{|z| \geqslant 1/\varepsilon\}$ for all ε small enough. On the other hand, in Case I, the error $f_1 - \pi_{\vec{n}}^{(1)}$ is at least geometrically big on compact subsets of Ω_{201}^-, see Figure 3(a), (it could be infinite if the elements of $\mathcal{D}_n$ belong to $\mathfrak{R}^{(0)}$ and project onto this component) and the error $f_2 - \pi_{\vec{n}}^{(2)}$ is at least geometrically big on compact subsets of Ω_{201}^+. In Case III, both components of the approximant diverge in Ω_{102} and in Case II there are no divergence domains.

As to the zeroes of the functions, it can be deduced from Theorem 3 and (4.5) that $Q_{\vec{n}}$ must vanish in $\mathcal{N}_\delta$ and $R_{\vec{n}}^{(i)}$ must vanish in $\mathcal{N}_\delta^{(i)}$, which is precisely the phenomenon of overinterpolation first observed in Nikishin systems.

5 MULTIPLE ORTHOGONAL POLYNOMIALS

The basis of our approach to asymptotics of Hermite-Padé approximants lies in their connection with multiple orthogonal polynomials. It is quite simple to verify that if the functions f_i are of the form (4.1), then (1.2) is fulfilled if and only if

$$\int_{F_i} Q_{\vec{n}}(x) x^k \rho_i(x)\, dx = 0, \quad k \in \{0, \dots, n_i - 1\}. \tag{5.1}$$

Moreover, the linearized error functions $R_{\vec{n}}^{(i)}$ admit the following integral representation:

$$R_{\vec{n}}^{(i)}(z) = \frac{1}{2\pi i} \int_{F_i} \frac{Q_{\vec{n}}(x)\rho_i(x)}{x - z}\, dx. \tag{5.2}$$

The analysis of the system (5.1)–(5.2) then proceeds via its reformulation as a matrix Riemann-Hilbert problem. This fundamental fact in the theory of orthogonal polynomials was first revealed by Fokas, Its, and Kitaev [18, 19] and the extension to multiple orthogonal polynomials was given in [37]. Set $\vec{n}_1 := (n-1, n)$ and $\vec{n}_2 := (n, n-1)$, and assume that the index n is such that

$$m_n^{(i)} R_{\vec{n}_i}^{(i)} = z^{-n} + \cdots \tag{5.3}$$

for some constants $m_n^{(i)}$. Under condition (5.3), the matrix

$$\mathbf{Y} := \begin{pmatrix} Q_{\vec{n}} & R_{\vec{n}}^{(1)} & R_{\vec{n}}^{(2)} \\ m_n^{(1)} Q_{\vec{n}_1} & m_n^{(1)} R_{\vec{n}_1}^{(1)} & m_n^{(1)} R_{\vec{n}_1}^{(2)} \\ m_n^{(2)} Q_{\vec{n}_2} & m_n^{(2)} R_{\vec{n}_2}^{(1)} & m_n^{(2)} R_{\vec{n}_2}^{(2)} \end{pmatrix} \tag{5.4}$$

solves the following Riemann-Hilbert Problem (RHP-$\mathbf{Y}$):

(a) $\mathbf{Y}$ is analytic in $\mathbb{C} \setminus [-1,1]$ and

$$\lim_{z \to \infty} \mathbf{Y}(z)\, \mathsf{diag}\left(z^{-2n}, z^n, z^n\right) = \mathbf{I},$$

where $\mathsf{diag}(\cdot,\cdot,\cdot)$ is the diagonal matrix and $\mathbf{I}$ is the identity matrix;

(b) $\mathbf{Y}$ has continuous traces on $(-1,1) \setminus \{\pm a\}$ that satisfy $\mathbf{Y}_+ = \mathbf{Y}_- \mathbf{J}(\chi_1\rho_1, \chi_2\rho_2)$, where

$$\mathbf{J}(x,y) = \begin{pmatrix} 1 & x & y \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \tag{5.5}$$

and χ_i is the indicator function of F_i;

(c) $\mathbf{Y}(z) = \mathcal{O}\left(\log|z-e|\right)$ as $[-1,1] \not\ni z \to e$ for $e \in \{\pm1, \pm a\}$[4].

Vice versa, if RHP-Y is solvable, then the solution is necessarily of the form (5.4) and (5.3) holds. To prove Theorem 9, we then follow the framework of the non-linear steepest descent method for matrix Riemann-Hilbert problems, first introduced in the 2×2 case by Deift and Zhou [14]. The proof of Theorem 9 is carried out in Sections 8–10.

6 GEOMETRY

This section is devoted to proving Theorems 1 and 3 together with Proposition 2. In Section 6.1 we establish that $\mathfrak{R}$ can indeed be realized as in Figure 1. In Section 6.2 we justify the the choice of the parameter p, thus, finishing the proof of Theorem 1, while simultaneously proving Proposition 2. Finally, we prove Theorem 3 in Section 6.3.

6.1 *Realization of* $\mathfrak{R}$

It can be readily computed that the discriminant of (2.1) is equal to

$$\begin{aligned} D(z) &= 108A(z)\left[B_2^3(z) - A(z)B_1^2(z)\right] \\ &= 108A(z)\left[(1+a^2-3p^2)z^4 + (3p^4-a^2)z^2 - p^6\right]. \end{aligned} \tag{6.1}$$

Assume first that we are in Case I, i.e.,

$$a \in \left(0, \frac{1}{\sqrt{2}}\right) \quad \text{and} \quad p \in \left(a, \sqrt{\frac{1+a^2}{3}}\right). \tag{6.2}$$

Since the polynomial $B_2^3 - AB_1^2$, which is symmetric and of degree 4, is negative at the origin and has positive leading coefficient, it follows that it has four zeros, which we denote by $\pm b$ and $\pm ic$, where $b, c > 0$. Furthermore, $b \in (a,p)$ since $B_2^3 - AB_1^2$ is positive at p and negative at a. Observe that if a point is a branch point of h of order 3 (all three branches coincide) and h is finite at this point, then necessarily all three branches are equal to zero there. Hence, $\pm b, \pm ic$ are branch points of order 2. Furthermore, the first equation in (2.2) implies that neither of the points $\pm1, \pm a$ can be a pole of one the branches while the second equation implies that the branches cannot have a cubic root singularity there. Hence, the points $\pm1, \pm a$ are branch points of order 2, two branches are infinite at them and one is finite.

It follows from the above discussion that we can analytically continue the branches h_k so that the inequalities in (2.4) hold for $x > 1$. At 1 two branches blow up and, of course, all three add up to zero. This is possible only if h_0 tends to ∞, h_2 tends to $-\infty$, and h_1 remains bounded. Thus, 1 is a branch point joining $\mathfrak{R}^{(0)}$ and $\mathfrak{R}^{(2)}$. It can easily be seen from (2.1) that all the branches must satisfy

$$h_k(z) = \overline{h_k(\bar{z})}. \tag{6.3}$$

Therefore, all the branch cuts must be conjugate-symmetric. Thus, the branch cut starting at 1 must end at b. That is, $h_{0\pm} = h_{2\mp}$ on $(b,1)$, which immediately implies

$$(h_0 - h_2)_+ + (h_0 - h_2)_- \equiv 0 \tag{6.4}$$

on $(b,1)$. Moreover, (6.3) implies that the traces above are purely imaginary. As h_0, h_2 are unbounded near 1 and bounded near b, one has

$$(h_0 - h_2)^2(x) = \frac{x-b}{x-1} f_1^2(x), \tag{6.5}$$

where f_1 is holomorphic, non-vanishing, and real on (a,∞). As f_1 must be positive for $x > 1$ and is non-vanishing, it is, in fact, positive for $x > a$. Therefore, $(h_0 - h_2)(x) > 0$,

---

[4] In fact, in each case the entries of at least two columns remain bounded. However, the above simplification does not affect the forthcoming analysis.

$x \in (a,b) \cup (1,\infty)$. Moreover, since h_1 is real and non-vanishing for $x > a$ and is negative for x large enough by (2.3), h_1 is negative for all $x > a$. Thus,

$$h_0(x) > h_2(x) > h_1(x), \quad x \in (a,b). \tag{6.6}$$

As in the case of 1, two branches are infinite at a and one is finite. The inequalities in (6.6) imply that the unbounded branches are h_0 and h_1 and therefore a is a branch point between $\mathfrak{R}^{(0)}$ and $\mathfrak{R}^{(1)}$. The branch cut is $(-a,a)$ since it must be along the real axis. That is, $h_{0\pm} = h_{1\mp}$ on $(-a,a)$ and

$$(h_0 - h_1)_+ + (h_0 - h_1)_- \equiv 0 \tag{6.7}$$

on $(-a,a)$ where the traces are purely imaginary. As h_0, h_1 are unbounded near $\pm a$, one has

$$(h_0 - h_1)^2(x) = \frac{f_a^2(x)}{x^2 - a^2}, \tag{6.8}$$

where f_a is holomorphic, non-vanishing, and real on $(-b,b)$. The function f_a is positive on (a,b) according to (6.6) and therefore is positive on $(-b,b)$. Hence, $(h_0 - h_1)(x) < 0$ for $x \in (-b,-a)$. Since both branches blow up at $-a$, one has

$$h_1(x) > h_2(x) > h_0(x), \quad x \in (-b,-a). \tag{6.9}$$

Furthermore, it is quite simple to deduce from (2.1) that the branches h_k must satisfy $h_k(-x) = -h_{j_k}(x)$ for all $k \in \{0,1,2\}$, where $j_k \in \{0,1,2\}$ depends on k. According to (6.6) and (6.9), the considered continuations of h_k satisfy $j_k = k$ for $|x| \in (a,b)$. Therefore, $-b$ is a branch point for h_0 and h_2 as well as -1. In particular, (6.4) remains valid for $x \in (-1,-b)$. Hence,

$$(h_0 - h_2)^2(x) = \frac{x+b}{x+1} f_{-1}^2(x), \tag{6.10}$$

where f_{-1} is holomorphic, non-vanishing, and real on $(d,-a)$ for some $d < -1$. From (6.9), we know that f_{-1} is negative on $(-b,-a)$ and therefore it is negative on $(d,-a)$. Thus, $(h_0 - h_2)(x) < 0$ for $x \in (d,-1)$. This and the blowing up of h_0 and h_2 at -1 imply that

$$h_2(x) > h_1(x) > h_0(x), \quad x \in (d,-1). \tag{6.11}$$

On the other hand, write

$$h_i(z) = -\frac{1}{z} + \frac{\alpha_i}{z^2} + \cdots \tag{6.12}$$

for $i \in \{1,2\}$. Plugging this expansion into (2.1) and considering the $1/z$ term on the left-hand side, we get that

$$\alpha_i^2 = \frac{1+a^2}{3} - p^2 > 0. \tag{6.13}$$

This means that the inequality $h_1(x) > h_2(x)$ holds for all $|x|$ large enough. That is,

$$h_1(x) > h_2(x) > h_0(x), \quad x \in (-\infty, d'),$$

where necessarily $d' < d$. As there are no branch points between d' and d, there should be a branch cut passing between them and this cut should necessarily be between $\mathfrak{R}^{(1)}$ and $\mathfrak{R}^{(2)}$. In other words, $\pm ic$ are branch points of h_1 and h_2. This finishes the proof of the claim that $\mathfrak{R}$ can be realized as in Figure 1(a) in Case I.

Assume now that we are in Case II, i.e.,

$$a = p = 1/\sqrt{2}.$$

Then the discriminant of (2.1) is equal to $D(z) = 27(z^2-1)(z^2-1/2)^2$. As before, ± 1 are branch points of order 2. Furthermore, we know from the third identity in (2.2) that some of the branches are unbounded near $\pm 1/\sqrt{2}$. However, if the branching were of order 2, the left-hand side of the second relation in (2.2) would be unbounded near $\pm 1/\sqrt{2}$, but it is bounded there. Hence, $\pm 1/\sqrt{2}$ are branch points of order 3.

Plugging a power expansion for h_i, $i \in \{1,2\}$, into (2.1), one can compute that

$$h_i(z) = -\frac{1}{z} + \frac{\beta_i}{z^3} + \cdots, \tag{6.14}$$

where the β_i's are solutions of $\beta^2 + \beta + 1/6 = 0$. In particular, $(h_1 - h_2)(z)z^3 = 1/\sqrt{3} + \mathcal{O}(1/z)$ for all z large. Then, by repeating the initial steps of the analysis for Case I, we see that (2.4) extends for all $x > 1$ and that

$$h_2(x) > h_1(x) > h_0(x), \quad x \in (-\infty, -1). \tag{6.15}$$

Therefore, $(-1, -1/\sqrt{2})$ and $(1/\sqrt{2}, 1)$ are the branch cuts for h_0 and h_2. Around the point $1/\sqrt{2}$ it can be directly verified that (2.1) is solved by the following Puiseux series:

$$h(z;\xi) = \frac{1}{\sqrt{1-z^2}}\left[-\xi\left(z - \frac{1}{\sqrt{2}}\right)^{-1/3} H^{1/3}(z) + \xi^2\left(z - \frac{1}{\sqrt{2}}\right)^{1/3} H^{-1/3}(z)\right], \tag{6.16}$$

where ξ is any solution of $\xi^3 = 1$, $H(z) := \big(1 + 2z\sqrt{1-z^2}\big)/\big(2z + \sqrt{2}\big)$, and all the roots are principal. Since h_1 is negative and holomorphic for $x > 1/\sqrt{2}$, one finds that $h_1(z) = h(z;1)$ locally around $1/\sqrt{2}$. On the other hand,

$$(h_0 - h_2)^2(x) = \frac{f^2(x)}{x^2 - 1},$$

where $f(x)$ is non-vanishing and holomorphic for $|x| > 1/\sqrt{2}$. Since $f(x) > 0$ for $x > 1$, we get that $f(x) > 0$ for $x > 1/\sqrt{2}$ and

$$h_{0\pm}(x) = h_{2\mp}(x) = -\frac{1}{2}h_1(x) \mp i\frac{f(x)}{\sqrt{1-x^2}}, \quad x \in \big(1/\sqrt{2}, 1\big). \tag{6.17}$$

Thus, h_{0+} has values in the fourth quadrant and h_{0-} has values in the first quadrant. As the first summand in (6.16) is dominant around $1/\sqrt{2}$, we can conclude that

$$h_0(z) = \begin{cases} h\big(z; e^{2\pi i/3}\big), & \operatorname{Im}(z) > 0, \\ h\big(z; e^{4\pi i/3}\big), & \operatorname{Im}(z) < 0, \end{cases} \quad \text{and} \quad h_2(z) = \begin{cases} h\big(z; e^{4\pi i/3}\big), & \operatorname{Im}(z) > 0, \\ h\big(z; e^{2\pi i/3}\big), & \operatorname{Im}(z) < 0, \end{cases} \tag{6.18}$$

locally around $1/\sqrt{2}$. From this it is easy to see that h_2 is holomorphic across the interval $\big(-1/\sqrt{2}, 1/\sqrt{2}\big)$ and this interval is the branch cut for h_1 and h_0.

Finally, assume that we are in Case III, that is,

$$a \in \left(\frac{1}{\sqrt{2}}, 1\right) \quad \text{and} \quad p = \sqrt{\frac{1+a^2}{3}} < a.$$

In this case $B_2^3 - AB_1^2$ is a polynomial of degree 2 which has two roots $\pm b$ satisfying $b \in (p, a)$. Exactly as in Case I, we see that all the branch points, namely $\{\pm 1, \pm a, \pm b\}$, are of order 2. Furthermore, the same reasoning as in Case I gives that (6.4) holds on $(a, 1)$. Since h_0 and h_2 are unbounded at both 1 and a, we get that

$$(h_0 - h_2)^2(x) = \frac{f_1^2(x)}{(x-1)(x-a)}, \tag{6.19}$$

where f_1 is holomorphic, non-vanishing, and real on (b, ∞). Since f_1 is positive for $x > 1$ and hence for $x > b$, we can conclude that $(h_0 - h_2)(x) < 0$ for $x \in (b, a)$. The blowing up of h_0 and h_2 at a implies that

$$h_2(x) > h_1(x) > h_0(x), \quad x \in (b, a). \tag{6.20}$$

It further follows from the third equation in (2.2) that two branches of h are negative and one branch is positive on (b, a). The inequalities in (6.20) show that the negative branches are h_0 and h_1. This, in turn, implies that b is a branch point of h_0 and h_1 and so is $-b$. Hence, (6.7) holds on $(-b, b)$. As all the branches are bounded at $\pm b$, we have that

$$(h_0 - h_1)^2(x) = (x^2 - b^2)f_b^2(x) \tag{6.21}$$

for $x \in (-a, a)$, where f_b is holomorphic, non-vanishing, and is negative on (b, a). Therefore, it is negative on the whole interval $(-a, a)$ and we get that $(h_0 - h_1)(x) > 0$ for $x \in (-a, -b)$. As before, the third equation in (2.2) implies that two branches of h are positive and one branch is negative on $(-a, -b)$. Moreover, it also implies that $h_2(0) = 0$. As $h_2(x) > 0$ for $x > 0$ and it has no other zeros, it must be the negative branch. Thus,

$$h_0(x) > h_1(x) > h_2(x), \quad x \in (-a, -b). \tag{6.22}$$

Now, as the branches that meet at $-a$ are unbounded, they must be h_0 and h_2 by (6.22). Hence, (6.4) holds on $(-1, -a)$ and we have that

$$(h_0 - h_2)^2(x) = \frac{f_{-1}^2(x)}{(x+1)(x+a)}, \tag{6.23}$$

where f_{-1} is holomorphic, non-vanishing, and positive on $(-a, -b)$. As before, this means that f_{-1} is positive for all $x < -b$ and (6.15) holds in this case as well. This finishes the proof of the claim that $\mathfrak{R}$ can be realized as in Figure 1(c) in Case III.

6.2 *Choice of the Parameter*

We start with Cases II and III as they are much simpler. Here we show that for the choice of the parameter p as in Theorem 1 the condition (2.6) is fulfilled. That is, the period of the Nuttall differential $d\mathcal{N}$ over any given chain on $\mathfrak{R}$ is purely imaginary. The latter simplifies to showing that the periods of $d\mathcal{N}$ on the cycles of a homology basis are purely imaginary. In fact, (2.15) implies that both periods of $d\mathcal{N}$ are equal to πi.

In proving (2.15) we shall rely on the following observation: one has that $h_k(-z) = -h_{j_k}(z)$ for some $j_k \in \{0, 1, 2\}$, which can be deduced immediately from (2.1). In fact, we see from (2.4) and (6.15) that $h_k(-z) = -h_k(z)$ for all $k \in \{0, 1, 2\}$. This implies that

$$\omega_1 = -\frac{1}{2\pi i}\int_{\Delta_{21}} (h_{0+} - h_{0-})(x)\,dx = -\frac{1}{2\pi i}\int_{\Delta_{22}} (h_{0+} - h_{0-})(x)\,dx.$$

The sum of the last two integrals is equal to 1 by Cauchy's residue theorem applied to h_2 (recall that $h_{0\pm} = h_{2\mp}$ on Δ and $h_2(z) = -1/z + \mathcal{O}(1/z^2)$). This gives the desired conclusion about ω_1. Furthermore, from the choice of the $\boldsymbol{\alpha}$-cycle, see Figure 2(b), one has for Case III that

$$\tau_1 = \frac{1}{2\pi i}\left(\int_a^b h_0(x)\,dx + \int_b^{-b} h_{0+}(x)\,dx + \int_{-b}^{-a} h_0(x)\,dx + \int_{-a}^{a} h_2(x)\,dx\right).$$

As h_0 is an odd function, the sum of the first and the third integrals is equal to zero. Since h_2 is odd as well, the fourth integral is zero too. Using the symmetry considerations once more, we can get that

$$\int_b^{-b} h_{0+}(x)\,dx = \int_{-b}^{b} h_{0-}(x)\,dx.$$

Then by applying Cauchy's residue theorem to h_1 (recall that $h_1(z) = -1/z + \mathcal{O}(1/z^2)$), we see that

$$\begin{aligned}\tau_1 &= \frac{1}{4\pi i}\left(\int_b^{-b} h_{0+}(x)\,dx + \int_{-b}^{b} h_{0-}(x)\,dx\right)\\ &= \frac{1}{4\pi i}\left(\int_b^{-b} h_{1-}(x)\,dx + \int_{-b}^{b} h_{1+}(x)\,dx\right) = 1/2.\end{aligned}$$

In Case II, we have that

$$\tau_1 = \frac{1}{2\pi i}\left(\int_{1/\sqrt{2}}^{-1/\sqrt{2}} h_{0+}(x)\,dx + \int_{-1/\sqrt{2}}^{1/\sqrt{2}} h_2(x)\,dx\right),$$

and the conclusion $\tau_1 = 1/2$ follows from an analogous symmetry argument. This finishes the proof for Cases II and III of Theorem 1.

In Case I we again start with (2.14). The symmetry of the surface implies in this case that h_0 is an odd function, i.e., $h_0(-z) = -h_0(z)$, the functions h_i, $i \in \{1,2\}$, are odd within the bounded domain delimited by Δ_0 and $-\Delta_0 := \{z : -z \in \Delta_0\}$, and $h_1(-z) = -h_2(z)$ for z within the unbounded domain delimited by Δ_0 and $-\Delta_0$. Then it follows from (2.3) and the Cauchy residue theorem that

$$\begin{aligned} 2 &= -\frac{1}{2\pi i}\int_{\Delta_2\cup\Delta_1}(h_{0+}-h_{0-})(x)\,dx \\ &= -\frac{1}{2\pi i}\int_{\Delta_2}(h_{0+}-h_{2+})(x)\,dx - \frac{1}{2\pi i}\int_{\Delta_1}(h_{0+}-h_{1+})(x)\,dx \\ &= \frac{1}{2\pi}\int_{\Delta_{21}}\big(-f_{-1}(x)\big)\sqrt{\frac{-b-x}{x+1}}\,dx + \frac{1}{2\pi}\int_{\Delta_1}\frac{f_a(x)}{\sqrt{z^2-x^2}}\,dx + \frac{1}{2\pi}\int_{\Delta_{22}}f_1(x)\sqrt{\frac{x-b}{1-x}}\,dx, \end{aligned}$$

where we used the notation from (6.5), (6.8), and (6.10). The analysis right after (6.5), (6.8), and (6.10) implies that each of the last three integrals is positive. From the definition of our homology basis, it can easily be seen that the first integral is equal to ω_1, the second one is equal to ω_2, and the third is equal to the first as h_0 is an odd function. That is, $\omega_i > 0$ and $2\omega_1 + \omega_2 = 2$. The latter clearly implies the first relation in (2.14) and the fact that $\omega = \omega_1 \in (0,1)$. Applying now the Cauchy residue theorem to h_2, we get that

$$\begin{aligned} 1 &= \frac{1}{2\pi i}\int_{\Delta_2}(h_{2+}-h_{2-})(x)\,dx + \frac{1}{2\pi i}\int_{\Delta_0}(h_{2+}-h_{2-})(x)\,dx \\ &= 2\omega_1 + \frac{1}{2\pi i}\int_{\Delta_0}(h_{2+}-h_{1+})(x)\,dx, \end{aligned}$$

where Δ_0 is oriented from $-ic$ to ic. Hence, we can conclude that $\omega_1 \in (1/2, 1)$, if we show that the last integral is negative. Since $h_{2+} - h_{1+}$ is a trace of a holomorphic function, we can deform the path of integration to get

$$\begin{aligned} \frac{1}{2\pi i}\int_{\Delta_0}(h_{2+}-h_{1+})(x)\,dx &= -\frac{1}{2\pi i}\left(\int_{-i\infty}^{-ic}+\int_{ic}^{i\infty}\right)(h_2(t)-h_1(t))\,dt \\ &= -\frac{1}{2\pi}\left(\int_{-\infty}^{-c}+\int_{c}^{\infty}\right)(h_2(ix)-h_1(ix))\,dx \\ &= -\frac{1}{\pi}\int_{c}^{\infty}(h_2(ix)-h_1(ix))\,dx, \end{aligned} \tag{6.24}$$

where we used the symmetry $h_2(-z) = -h_1(z)$ to get the last equality. Notice also that the branches satisfy $h_k(z) = \overline{h_k(\bar{z})}$ as follows directly from (2.1). Hence,

$$h_2(ix) - h_1(ix) = h_2(-ix) - h_1(-ix) = \overline{h_2(-\overline{ix}) - h_1(-\overline{ix})} = \overline{h_2(ix) - h_1(ix)}$$

for $x > c$. Hence, this difference is real there. Moreover, $h_2(ix) - h_1(ix) > 0$ for all x large as follows from (6.12) and (6.13). Since the difference $h_2 - h_1$ can be equal to zero only at the branch points of $\mathfrak{R}$, $h_2(ix) - h_1(ix) > 0$ for all $x > c$, which shows that the integral in (6.24) is negative as desired.

To prove the second relation in (2.14), observe that our choice of the homology basis can be made so that the $\boldsymbol{\alpha}$-cycles are contained within the bounded domain delimited by Δ_0 and $-\Delta_0$, see Figure 2(a). Moreover, they can freely be deformed within the domain of holomorphy of $d\mathcal{N}$. Thus, it follows from (2.5) and (2.12) that

$$\begin{aligned} 2\pi i\tau_1 &= \int_{-a}^{-b}h_0(x)\,dx + \int_{-b}^{0}h_2(x)\,dx + \int_{0}^{-ic}h_2(x)\,dx + \int_{-ic}^{0}h_1(x)\,dx + \int_{0}^{-a}h_{0-}(x)\,dx \\ &= \int_{a}^{b}h_0(x)\,dx + \int_{b}^{0}h_2(x)\,dx + \int_{0}^{ic}h_2(x)\,dx + \int_{ic}^{0}h_1(x)\,dx + \int_{0}^{a}h_{0+}(x)\,dx \\ &= -2\pi i\tau_2, \end{aligned}$$

where we used the fact $h_k(-z) = -h_k(z)$ with the bounded domain delimited by Δ_0 and $-\Delta_0$, which, in particular, implies that $h_{1-}(-x) = h_{1+}(x)$ for $x \in (-a, a)$. This finishes the proof of (2.14). It only remains to show that there exists a choice of the parameter p in (2.1) so that τ from (2.14) is real.

Showing that there is a choice of the parameter $p \in (a, \sqrt{(1+a^2)/3})$ such that τ in (2.14) is real, is equivalent to proving that $I = 0$, where

$$I := \mathrm{Re}\left(\oint_{\boldsymbol{\alpha}_2} h(z)\,dz\right). \tag{6.25}$$

In order to prove (6.25) we consider the limiting values of $I = I(p)$ as $p \to \sqrt{(1+a^2)/3}$ and $p \to a$. If they have opposite signs, then clearly such a choice of p is indeed possible.

We start with the case $p \to \sqrt{(1+a^2)/3}$. Define

$$\begin{cases} N_k(z;p) & := & \mathrm{Re}\left(\int_b^z h_k(x)\,dx\right), \quad k \in \{0,2\}, \\ N_1(z;p) & := & \mathrm{Re}\left(\int_a^z h_1(x)\,dx\right) + N_0(a;p), \end{cases} \qquad z \in \big\{\mathrm{Re}(z), \mathrm{Im}(z) \geqslant 0\big\}.$$

Then it obviously holds that $I(p) = N_1(ic;p) - N_2(ic;p)$. In Section 6.3 further below we shall argue that

$$N(\boldsymbol{z};p^*) := \mathrm{Re}\left(\int^{\boldsymbol{z}} h(\boldsymbol{x};p^*)\,dx\right), \quad p^* := \sqrt{(1+a^2)/3}, \tag{6.26}$$

is a well defined harmonic function on the Riemann surface of $h(\cdot;p^*)$ and that

$$N\big(\infty^{(1)};p^*\big) - N\big(\infty^{(2)};p^*\big) < 0. \tag{6.27}$$

As $I(p)$ depends continuously on the parameter p, we can conclude that $I(p^*) < 0$.

Let now $p = a$. In this case equation (2.1) becomes

$$(z^2-1)(z^2-a^2)\,h^3 - 3(z^2-a^2)\,h - 2z = 0\,, \quad a^2 < 1/2. \tag{6.28}$$

The branch points with projections a and b of the curve (6.28) merge together into a triple branch point with projection a (this can be observed directly from (6.1)). To verify that $I(a) > 0$, we deform the cycle $\boldsymbol{\alpha}_2 = \boldsymbol{\alpha}_2(a)$ into a cycle $\boldsymbol{\alpha}$ which is involution-symmetric and whose projection from $\mathfrak{R}^{(1)}$, say α, is as on Figure 5. That is, α emanates from a into the first quadrant along some special arc $z(t)$, $t \in [0, t_-]$, and then proceeds along the imaginary axis from $z(t_-)$ down to ic.

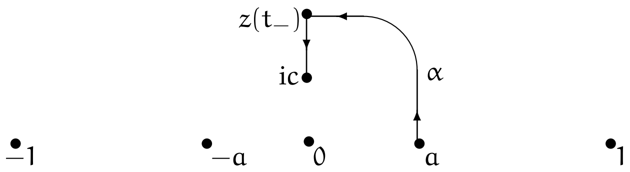

FIGURE 5. Contour α for the limiting case $p = a < 1/\sqrt{2}$.

As in (6.24) one has $\overline{h_i(\bar{z};a)} = h_i(z;a)$ and $h_1(-z) = -h_2(z)$ for all z large (and hence for all $z \in (ic, i\infty)$), which leads to the same conclusion that $(h_1 - h_2)(z)$ is real for $z \in (ic, i\infty)$ and therefore the real part of the integral of this difference on $[ic, i\infty)$ is equal to zero. Hence, we get that

$$I(a) = \mathrm{Re}\left(\int_\alpha (h_1(z;a) - h_2(z;a))\,dz\right).$$

Therefore, in order to complete the proof of Theorem 1, it remains to show that there exists an arc $z(t)$, such that

$$\begin{cases} z(0) = a, \quad \mathrm{Re}(z(t_-)) = 0, \quad \mathrm{Im}(z(t_-)) > c, \\ \mathrm{Re}\big((h_1 - h_2)(z(t))z'(t)\big) > 0, \quad t \in (0, t_-). \end{cases} \tag{6.29}$$

To construct this arc we use a parametrization of the algebraic curve (6.28). This parametrization was suggested in [11] and it has the form

$$\left\{\begin{aligned} h &= -i\left(\xi t + \frac{1}{\xi t}\right) C(t) \\ z &= \frac{t^3}{1-t^6}\left(\tilde{a}_-(t) + i\tilde{a}_+(t)\right) \end{aligned}\right. , \quad \xi^3 = 1, \quad t \in \mathbb{C}, \tag{6.30}$$

where

$$\tilde{a}_\pm(t) := \sqrt{\pm(1-a^2) \mp a^2 t^{\pm 6}}\,, \quad C(t) := \frac{\tilde{a}_+(t) + it^6\tilde{a}_-(t)}{(1-a^2)(1+t^6)}. \tag{6.31}$$

Since the expression for h in (6.30) has the Cardano form

$$h = \xi A + \xi^{-1}B, \quad A = -itC, \quad B = -\frac{i}{t}C,$$

the equivalence of (6.30) and (6.28) can be written (using the Vieta relations) as

$$\left\{\begin{aligned} &-AB = C^2 = -\frac{1}{z^2-1} \\ &A^3 + B^3 = iC^3\left(t^3 + t^{-3}\right) = \frac{2z}{(z^2-1)(z^2-a^2)}. \end{aligned}\right.$$

With some work one can verify that plugging in the expression for $C(t)$ from (6.31) and the expression for $z(t)$ from (6.30) into the above equations produces an identity, which proves that (6.30) is indeed a parametrization of (6.28), (for details see [11]). Observe that

$$\tilde{a}_\pm(t) \geqslant 0, \quad t \in [0, t_-], \quad t_- := \left(\frac{a^2}{1-a^2}\right)^{1/6}, \tag{6.32}$$

and that the parametrization (6.30) defines a Jordan arc with end points

$$z(0) = a \quad \text{and} \quad z(t_-) = \frac{ia}{\sqrt{1-2a^2}}, \quad \text{while} \quad ic = \frac{ia^2}{\sqrt{1-2a^2}},$$

As $a > a^2$, the first line of (6.29) is satisfied. The local analysis around the point a shows that h_1 is given by (6.30) with $\xi = (i\sqrt{3}-1)/2$ and for h_2 one needs to select $\xi = (-i\sqrt{3}-1)/2$. Then, after a tedious computation, we get

$$(h_1 - h_2)(z(t))z'(t) = \frac{3\sqrt{3}\,t}{t^4+t^2+1}\left(\frac{1-2a^2}{\tilde{a}_+\tilde{a}_-} - i\right).$$

Hence, the second line of (6.29) follows from (6.32) as $a^2 < 1/2$. This finishes the proof of Theorem 1 granted we can prove that $N(z; p^*)$ in (6.26) is a well defined harmonic function, which we do at the end of the upcoming subsection.

6.3 *The Regions* Ω_{ijk}

We start with two general observations that are consequences of the single-valuedness of $N(z)$ on $\mathfrak{R}$. First, the regions Ω_{ijk} could be equivalently defined by

$$\Omega_{ijk} := \left\{z : N_j(z) > N_i(z) > N_k(z)\right\},$$

and this definition does not depend on the initial point of integration chosen in (2.6) as changing the initial point results in adding the same constant to all N_k simultaneously. Secondly, let H be the analytic continuation of $h_1 - h_2$ from the point at infinity. Then H is an algebraic function and $\mathrm{Re}(H)$ is a well defined harmonic function on the Riemann surface of H. Hence, the set Γ is a subset of a projection of the zero level line of $\mathrm{Re}(H)$ to $\overline{\mathbb{C}}$. As such it cannot be dense in an open set.

We start with Case I. It will be convenient to consider a slightly different realization of $\mathfrak{R}$, namely, we shall suppose that

$$\Delta_0 = [-i\infty, -ic] \cup [ic, i\infty]. \tag{6.33}$$

Our first goal is to show that Γ in this case has the form as shown in Figure 6. It follows from our first observation that lines Γ_{ij} emanating from a projection of a branch point $\boldsymbol{e}$ of $\mathfrak{R}$ can be described by

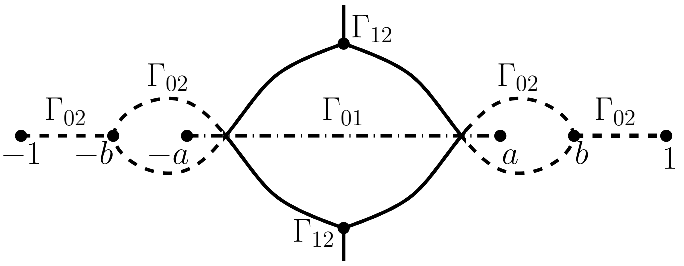

FIGURE 6. Case I: Γ_{12} - solid lines, Γ_{02} - dashed lines, and Γ_{01} - dotted dashed line.

$$0 = \operatorname{Re}\left(\int_e^z (h_i - h_j)(x)\,dx\right),$$

for $z \in \Gamma_{ij}$ locally around e. That is, Γ_{ij} is a trajectory of a quadratic differential $(h_i - h_j)^2(x)\,dx^2$. The local behavior of the trajectories is well known, [35]. This implies that exactly one line of the set Γ emanates from the points ± 1 and $\pm a$ ("hard edges") and exactly three lines (with angle $\pi/3$ between them) emanate from the points $\pm b$, $\pm ic$ ("soft edges").

In order to proceed, recall the inequalities (2.4) and (6.6) as well as the decompositions (6.5) and (6.8). Furthermore, it follows from (6.3) and the fact that $h_0(-z) = -h_0(z)$ that h_0 is purely imaginary on $i\mathbb{R}$. Analogously, we can conclude that h_i, $i \in \{1, 2\}$, are purely imaginary on $(-ic, 0) \cup (0, ic)$.

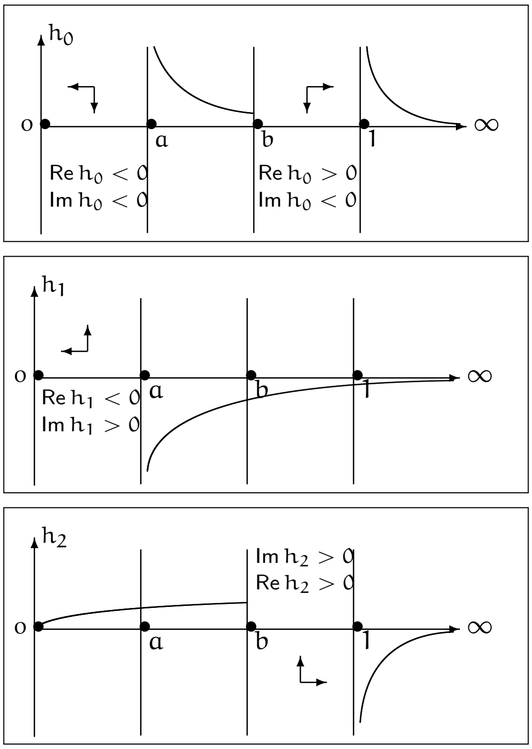

FIGURE 7. Behavior of the branches h along the upper bank of $\mathbb{R}_+$.

It follows immediately from (6.5) and (6.6), by choosing the initial point of integration to be a in (2.6), that

$$N_0(x) = N_1(x), \quad x \in \Delta_1, \quad \text{and} \quad N_0(x) > N_1(x), \quad x \in (a, b). \tag{6.34}$$

Similarly, by choosing the initial point of integration in (2.6) to be b, we deduce from (6.8) and (6.6) that

$$N_0(x) = N_2(x) > N_1(x), \quad x \in \Delta_{22}, \quad \text{and} \quad N_2(x) > N_0(x), \quad x \in (a,b). \tag{6.35}$$

Hence, we get from the symmetry of the surface that

$$\Delta_1 \subset \Gamma_{01}, \quad \Delta_2 \subset \Gamma_{02}, \quad (-b,-a) \cup (a,b) \in \Omega_{201}. \tag{6.36}$$

Moreover we have

$$N_2(a) > N_0(a) = N_1(a), \quad N_2(b) = N_0(b) > N_1(b). \tag{6.37}$$

To conclude our qualitative analysis based on Figure 7, we continue the integration beyond the points 1 (to the right) and a (to the left). We get that there exists $d_1 > 1$ and $d_a > 0$ such that

$$(1, d_1) \in \Omega_{021} \quad \text{and} \quad N_0(x) = N_1(x) > N_2(x), \quad x \in (d_a, a]. \tag{6.38}$$

Indeed, if we start integrating from 1 in the positive direction, then N_0 increases and N_2 decreases. Thus, (6.38) follows from (6.35) and (6.36) by continuity. We summarize the order of the branches of N along $\mathbb{R}_+$ in Figure 8.

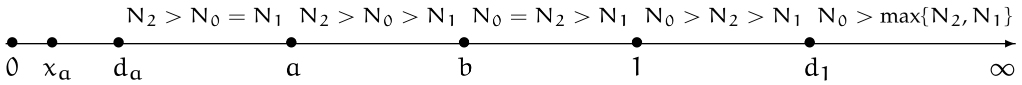

FIGURE 8. The result of the qualitative analysis of the branches of N along $\mathbb{R}_+$.

We note that N_2 decreases if its argument moves from d_a to the left while N_0 and N_1 increase, see Figure 7. Thus, it is possible that there exists $x_a \in (0, d_a)$ such that

$$N_0(x_a) = N_1(x_a) = N_2(x_a). \tag{6.39}$$

Moreover, if such a point exists, it is unique. In order to prove the last claim, set

$$d\lambda_1(x) = \frac{f_a(x)}{\sqrt{a^2 - x^2}} \frac{dx}{2\pi}, \quad x \in (-a, a),$$

where the function f_a is positive and was defined in (6.8),

$$d\lambda_2(x) = \begin{cases} f_1(x)\sqrt{\dfrac{x-b}{1-x}}\dfrac{dx}{2\pi}, & x \in (b, 1), \\ -f_{-1}(x)\sqrt{\dfrac{-x-b}{1+x}}\dfrac{dx}{2\pi}, & x \in (-1, -b), \end{cases}$$

where the function f_1 is positive and was defined in (6.5) while and f_{-1} is negative and was defined in (6.10), and finally

$$d\lambda_0(x) = \pm(h_{1+} - h_{1-})(x)\frac{dx}{2\pi i}, \quad \pm x \in [ic, i\infty).$$

The measures λ_1, λ_2, and λ_0 are positive (for λ_{12} this claim follows from the discussion after (6.24) where one needs to recall that we deformed Δ_0 to be as in (6.33)). It further follows from (6.5), (6.8), (6.10), and Privalov's lemma [31, Sec. III.2] that

$$h_i(z) = \int \frac{d\lambda_i(x)}{x - z} - (-1)^i \int \frac{d\lambda_0(x)}{x - z}, \quad \text{and} \quad h_0(z) = -\int \frac{d(\lambda_1 + \lambda_2)(x)}{x - z}.$$

Since $h_k(z) = 2\partial_z N_k(z)$, we deduce that the branches N_i, $i \in \{1, 2\}$, have the following global representation

$$N_i(z) = V_i(z) - (-1)^i V_0(z) - c_i,$$

where $V_k(z) = -\int \log|z - t|\, d\lambda_k(t)$, $k \in \{0, 1, 2\}$. Notice that the symmetry of $\mathfrak{R}$ implies that λ_2 is an even measure. Therefore, in a complex neighborhood of $[-b, b]$ (which is the gap between two connected components of $\operatorname{supp}(\lambda_2)$), the potential V_2 has the form of a saddle such that on the imaginary axis $i\mathbb{R}$ it is an even, concave and decreasing function. Hence,

$$\frac{\partial^2 V_2(x)}{\partial x^2} > 0, \quad x \in [-b,b], \quad \text{and} \quad \frac{\partial^2 V_2(iy)}{\partial y^2} < 0, \quad y \in \mathbb{R}.$$

The same is true for V_0, that is,

$$\frac{\partial^2 V_0(x)}{\partial x^2} < 0, \quad x \in \mathbb{R}, \quad \text{and} \quad \frac{\partial^2 V_0(iy)}{\partial y^2} > 0, \quad y \in [-c,c].$$

Thus, N_2 is a convex function on $[-b,b]$. As $2N_1 = -N_2$ on $[-a,a]$, N_1 is a concave function on $[-a,a]$. Thus, inside $[-a,a]$, the inequality $N_1 > N_2$ can be true on the connected set only, i.e., on the interval $[-x_a, x_a]$, so (6.39) and the uniqueness claim are proved and we obtain

$$N_0 = N_1 > N_2 \quad \text{on} \quad (-x_a, x_a). \tag{6.40}$$

Now, consider the trajectory Γ_{12} (i.e., the set where $N_1 = N_2$) emanating from the point ic into $\{\operatorname{Re} z > 0\}$. It cannot cross the set $i\mathbb{R} \cup [1,\infty] \cup [-\infty,-1]$ as it would contradict the maximum principle for harmonic functions. Hence, the only possibility for Γ_{12} to cross $[0,1]$ is to cross it at x_a. Analogous considerations lead to the conclusion that the trajectory of Γ_{02} emanating from the point b to the lower half-plane arrives at x_a and coincides with the continuation of the considered trajectory Γ_{12}. Thus, we have that the three subarcs of Γ_{12} emanating from the point ic (resp. $-ic$) terminate at the points $i\infty$ (resp. $-i\infty$) and $\pm x_a$; three subarcs of Γ_{02} emanating from the point b (resp. $-b$) terminate at the points 1 (resp. -1) and $\pm x_a$; the trajectory Γ_{01} joins the points $-a$ and $+a$. That is, we have shown that the set Γ has indeed the form as in Figure 6.

The structure of Γ and the order of the branches $\{N_k\}_{k=0}^2$ on $\mathbb{R}$ (see Figure 8 and (6.40)) allow us to identify the decomposition of $\mathbb{C}\backslash\Gamma$ into $\cup\Omega_{ijk}$ like in Figure 9. It remains to deform the cut (6.33) to the one in Figure 3(a) while simultaneously interchanging indices 1 and 2 in the subscripts of Ω_{ijk} bounded by Δ_0 and $[-ic,-i\infty] \cup [ic,i\infty]$. This finishes the proof of the Case I of Theorem 3.

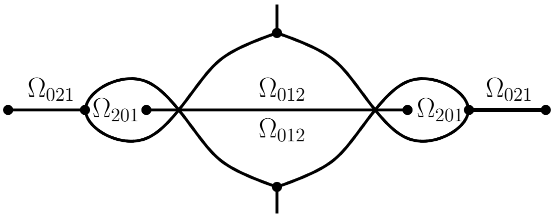

FIGURE 9. Case I: The sets Ω_{ijk} when $\Delta_0 = [-ic,-i\infty] \cup [ic,i\infty]$.

Now we prove Cases II and III of Theorem 3. Recall that we put $p = \sqrt{(1+a^2)/3}$ in (2.1) and therefore the imaginary branch points $\pm ic$ annihilate at infinity. Similar to Case I, we can use (6.17), (6.19), (6.21), and (6.23), to show that

$$N_i(z) = V_i(z) - c_i, \quad V_i(z) := -\int \log|z-t|\, d\lambda_i(t),$$

where λ_i is a positive measure supported inside of Δ_i, $i \in \{1,2\}$. Then the choice of the additive constant in (2.7) and the ordering of the branches N along $\mathbb{R}$ give us

$$\begin{cases} (2V_1+V_2)(t) - \gamma_1 \begin{cases} = 0, & t \in \operatorname{supp}(\lambda_1), \\ \geqslant 0, & t \in [-a,a], \end{cases} \\ \\ (2V_2+V_1)(t) - \gamma_2 \begin{cases} = 0, & t \in \operatorname{supp}(\lambda_2) \\ \geqslant 0, & t \in [-1,-a] \cup [a,1], \end{cases} \end{cases} \qquad \begin{cases} \gamma_1 = 2c_1 + c_2, \\ \gamma_2 = 2c_2 + c_1. \end{cases} \tag{6.41}$$

This type of vector-potential equilibrium problem is well-known in the theory of Hermite-Padé approximants and systems of measures $\{\lambda_1, \lambda_2\}$ which satisfy such equilibrium conditions are called Angelesco systems, [1, 27, 21]. Using the symmetry of the problem (6.41) with respect to the imaginary axis we can transform it to the following one. Set

$$\begin{aligned}\widetilde{V}_1(w) &:= \int_0^{a^2} \log\frac{1}{|w-x|}\, d\lambda_1(\sqrt{x}) \\ &= \frac{1}{2}\int_{-a}^{a} \log\frac{1}{|z^2-t^2|}\, d\lambda_1(t) = (V_1(z)+V_1(-z))/2 = V_1(z),\end{aligned}$$

where we used the change of variables $w = z^2$ and $x = t^2$. Analogously, we put

$$\widetilde{V}_2(w) := \int_{a^2}^{1} \ln\frac{1}{|w-x|}\, d\lambda_2(\sqrt{x}) = V_2(z), \quad w = z^2.$$

Thus, (with the same constants γ_i as in (6.41)) we have

$$\left\{\begin{aligned} &(2\widetilde{V}_1+\widetilde{V}_2)(x)-\gamma_1 \begin{cases} = 0 & x \in \operatorname{supp}(\lambda_1(\sqrt{x})) \cap [0,1], \\ \geqslant 0 & x \in [0, a^2], \end{cases} \\ &(2\widetilde{V}_2+\widetilde{V}_1)(x)-\gamma_2 \begin{cases} = 0 & x \in \operatorname{supp}(\lambda_2(\sqrt{x})) \cap [0,1], \\ \geqslant 0 & x \in [a^2, 1]. \end{cases} \end{aligned}\right. \tag{6.42}$$

Therefore,

$$N_i(z) = \widetilde{N}_i(w) := \widetilde{V}_i(w) - c_i, \quad w = z^2, \quad i \in \{1,2\}. \tag{6.43}$$

Angelesco systems (6.42) for two touching intervals $[0, a^2]$ and $[a^2, 1]$ (for any $a \in (0,1)$) are well studied, see [24, 22, 2, 6]. In particular, one knows that the regions Ω_{ijk} constructed for $\widetilde{N}_k(w)$ decompose $\overline{\mathbb{C}}$ as in Figure 10.

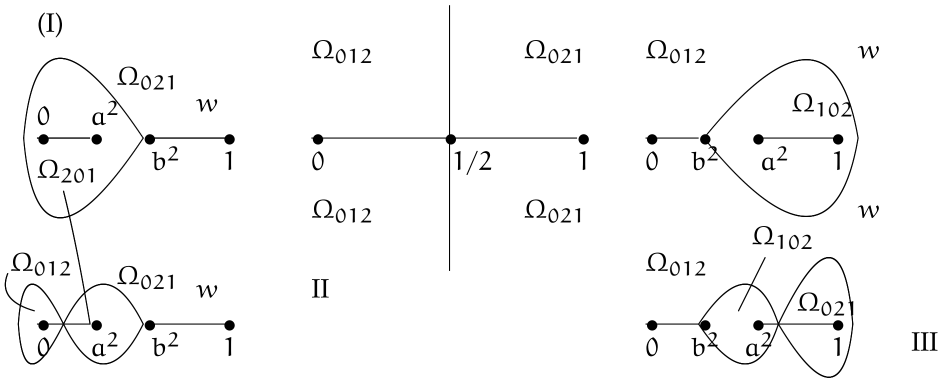

FIGURE 10. Domains Ω_{ijk} for $\widetilde{N}_k$. Case (I): $a^2 < 1/2$; Case II: $a^2 = 1/2$; Case III: $a^2 > 1/2$

Thus, if we plot images of the sets Ω_{ijk} from Figure 10 (Cases II and III) under the transformation $z = \sqrt{w}$, then (due to (6.43)) we obtain the corresponding sets from Figure 3 (b,c,d). This finishes the proof Theorem 3.

It remains to show that (6.26) defines single-valued harmonic function on the Riemann surface of $h(\cdot, p^*)$, $p^* = \sqrt{(1+a^2)/3}$, which satisfies (6.27). This follows from the fact we can obtain $N(\cdot; p^*)$ from $\widetilde{N}(\cdot; p^*)$ through the transformation $z^2 \to w$ and the latter can be computed via (6.42) and (6.43). The partition of $\mathbb{C}$ by the domains Ω_{ijk} for $\widetilde{N}$ is presented in Figure 10 [Case (I)]. Hence, the corresponding domains for N are distributed as in Figure 11, which finishes the proof of Theorem 1 and justifies the proof of Theorem 3.

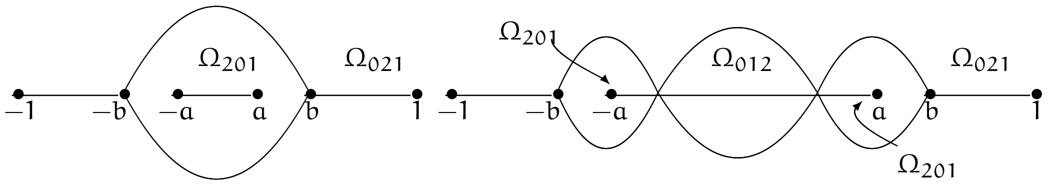

FIGURE 11. Sets Ω_{ijk} for (2.1) with $p = \sqrt{(1+a^2)/3}$ and $a < 1/\sqrt{2}$.

7 NUTTALL-SZEGŐ FUNCTIONS

This section is devoted to the construction of the Nuttall-Szegő functions of Theorems 6 and 7. Along the way we prove Propositions 4 and 5. For brevity, we shall use the following notation:

$$\mathfrak{R}_\alpha := \mathfrak{R} \setminus \bigcup_{i=1}^{g} \alpha_i \quad \text{and} \quad \mathfrak{R}_{\alpha,\beta} := \mathfrak{R} \setminus \bigcup_{i=1}^{g} (\alpha_i \cup \beta_i)\,.$$

7.1 *Abelian Differentials*

A holomorphic differential on $\mathfrak{R}$ is a differential of the form

$$d\Omega(\boldsymbol{z}) = f(\boldsymbol{z})\,dz,$$

where f is a rational function on $\mathfrak{R}$ whose *principal divisor* is of the form

$$(f) = \mathcal{D}_f + 2\left(\infty^{(0)} + \infty^{(1)} + \infty^{(2)}\right) - \sum_{\boldsymbol{e} \in \{\text{branch points of } \mathfrak{R}\}} \big(\{\text{order of branching at } \boldsymbol{e}\} - 1\big)\boldsymbol{e}, \tag{7.1}$$

for some integral divisor $\mathcal{D}_f$ of order $2g-2$. It is known that such rational functions (integrands of holomorphic differentials) form a subspace of dimension g. Hence, there exists precisely one such integrand (up to a multiplicative constant) when $g = 1$, and there exist 2 linearly independent ones when $g = 2$. It is further known that if f_1 and f_2 are distinct integrands of holomorphic differentials, then $\mathcal{D}_{f_1}$ and $\mathcal{D}_{f_2}$ have no element in common. Moreover, any $\boldsymbol{z} \in \mathfrak{R}$ has a unique complementary point, say $\hat{\boldsymbol{z}}$, such that $\mathcal{D}_{f_z} = \boldsymbol{z} + \hat{\boldsymbol{z}}$ for some holomorphic integrand f_z. When $g = 2$, the integral divisors $\mathcal{D}_f$ in (7.1) are exactly the special divisors mentioned before Proposition 5. Clearly, if $\mathcal{D}_{f_1}$ and $\mathcal{D}_{f_2}$ are any two special divisors, then $\mathcal{D}_{f_1} - \mathcal{D}_{f_2}$ is principal.

A point $\boldsymbol{z}$ is a Weierstrass point of a genus 2 surface $\mathfrak{R}$ if there exists a rational function on $\mathfrak{R}$ with a double pole at $\boldsymbol{z}$ and no other poles. Hence, $\boldsymbol{z}$ is a Weierstrass point if and only if $\hat{\boldsymbol{z}} = \boldsymbol{z}$. To find Weierstrass points it is enough to find a two-sheeted Riemann surface conformally equivalent to $\mathfrak{R}$. Indeed, Weierstrass points are mapped into Weierstrass points and the Weierstrass points of a two sheeted surface of genus 2 are precisely the branch points. It was shown in [10, Theorem 1.1] that $\mathfrak{R}$ is conformally equivalent to

$$Z^2 = A'(t)^2 - 4A(t)\big(3t^2 - (1+a^2) + 3p^2\big), \tag{7.2}$$

where A is the same polynomial as in (2.1) and the correspondence between the surfaces is given by[5]

$$\begin{cases} t = z + 1/h \\ Z = 2\big(3t^2 - (1+a^2) + 3p^2\big)/h + A'(t) \end{cases}$$

---

[5] One needs to replace h by $-h$ in (2.1) to get the correct correspondence with [10, Theorem 1.1].

for the uniformizing parameter $t \in \overline{\mathbb{C}}$. It follows from (6.12) and (6.13) that

$$t\left(\infty^{(2)}\right) = \sqrt{\frac{1+a^2}{3}} \quad \text{and} \quad Z^2\left(\infty^{(2)}\right) = A'\left(t\left(\infty^{(2)}\right)\right)^2.$$

As $Z\left(\infty^{(2)}\right) \neq 0$, it is not a branch point of (7.2) and hence $\infty^{(2)}$ is not a Weierstrass point of $\mathfrak{R}$, which is a conclusion we shall need later.

As just explained, $\mathfrak{R}$ has g linearly independent holomorphic differentials. Denote by

$$d\vec{\Omega} := \begin{cases} (d\Omega_1, d\Omega_2)^T, & g = 2, \\ d\Omega_1, & g = 1, \end{cases}$$

the column vector of such differentials or the unique differential normalized so

$$\oint_{\alpha_k} d\Omega_j = \delta_{jk},$$

where δ_{jk} is the usual Kronecker symbol. The differentials $d\Omega_k$ form a basis for the space of holomorphic differentials on $\mathfrak{R}$. The vector of analytic integrals $\vec{\Omega}$ defined before (3.1) is given by

$$\vec{\Omega}(\boldsymbol{z}) := \int_{\boldsymbol{e}_1}^{\boldsymbol{z}} d\vec{\Omega},$$

where $\boldsymbol{e}_1$ is the branch point of $\mathfrak{R}$ such that $\pi(\boldsymbol{e}_1) = 1$ (we could have chosen any other point to be the initial point for integration). The significance of this vector lies in Abel's theorem: if $\mathcal{D}_1$ and $\mathcal{D}_2$ are integral divisors, the divisor $\mathcal{D}_1 - \mathcal{D}_2$ is principal if and only if the orders of $\mathcal{D}_i$ coincide and

$$\vec{\Omega}(\mathcal{D}_1) \equiv \vec{\Omega}(\mathcal{D}_2) \quad \left(\text{mod periods } d\vec{\Omega}\right), \tag{7.3}$$

where $\vec{\Omega}(\mathcal{D}) := \sum_i n_i \vec{\Omega}(\boldsymbol{z}_i)$ for $\mathcal{D} = \sum_i n_i \boldsymbol{z}_i$.

In what follows we shall also use differentials $d\Omega_{\boldsymbol{z},\boldsymbol{w}}$ that are the normalized (that is, $\oint_{\alpha_i} d\Omega_{\boldsymbol{z},\boldsymbol{w}} = 0$, $1 \leqslant i \leqslant g$) abelian differentials of the third kind with simple poles at $\boldsymbol{z}$ and $\boldsymbol{w}$ of respective residues $+1$ and -1, and holomorphic otherwise.

7.2 *Cauchy Kernel on $\mathfrak{R}$*

To solve the boundary value problem stated in Theorem 6, we need a (discontinuous) Cauchy kernel suited for our purposes. Define $dC_{\boldsymbol{z}}$ to be the normalized third kind differential with three simple poles, say $\boldsymbol{z}, \boldsymbol{z}_1, \boldsymbol{z}_2$, assuming $\pi^{-1}(z) = \{\boldsymbol{z}, \boldsymbol{z}_1, \boldsymbol{z}_2\}$, which have respective residues $2, -1, -1$. It is quite simple to see that for any fixed $\boldsymbol{w}$ we have

$$dC_{\boldsymbol{z}} = 2d\Omega_{\boldsymbol{z},\boldsymbol{w}} - d\Omega_{\boldsymbol{z}_1,\boldsymbol{w}} - d\Omega_{\boldsymbol{z}_2,\boldsymbol{w}}.$$

Let $\boldsymbol{\gamma}$ be a chain on $\mathfrak{R}$ possessing projective involution. For each $\mathbf{t} \in \boldsymbol{\gamma}$ which is not a branch point of $\mathfrak{R}$, we shall denote by $\mathbf{t}^*$ another point on $\boldsymbol{\gamma}$ having the same canonical projection, i.e., $\pi(\mathbf{t}) = \pi(\mathbf{t}^*)$. When $\mathbf{t} \in \boldsymbol{\gamma}$ is a branch point of the surface, we simply set $\mathbf{t}^* = \mathbf{t}$.

Henceforth, fix $\boldsymbol{\gamma}$ as above and let λ be a Hölder continuous function on $\boldsymbol{\gamma}$. For simplicity, we shall also assume that the set $\pi(\boldsymbol{\gamma}) \cap \bigcup_{i=1}^g \pi(\boldsymbol{\alpha}_i)$ consists of finitely many points. Define

$$\Lambda(\boldsymbol{z}) := \frac{1}{6\pi i}\oint_{\boldsymbol{\gamma}} \lambda\, dC_{\boldsymbol{z}}, \qquad \boldsymbol{z} \in \mathfrak{R} \setminus \pi^{-1}\left(\pi\left(\boldsymbol{\gamma} \cup \bigcup_{i=1}^g \boldsymbol{\alpha}_i\right)\right).$$

The function Λ is holomorphic in the domain of its definition. Moreover, when $\boldsymbol{z} \to \boldsymbol{t} \in \boldsymbol{\alpha}_k^{\pm}$, one of the points $\boldsymbol{z}_i$, say $\boldsymbol{z}_1$, approaches $\boldsymbol{t}^* \in \boldsymbol{\alpha}_k^{\mp}$, while $\boldsymbol{z}_2$ does not approach any point on $\boldsymbol{\gamma} \cup \boldsymbol{\alpha}_k$ (projective involution property). Hence,

$$\begin{aligned} \Lambda^+(\boldsymbol{t}) - \Lambda^-(\boldsymbol{t}) &= \frac{1}{3}\left[\frac{2}{2\pi i}\oint_{\boldsymbol{\gamma}} \lambda \left(d\Omega^+_{\boldsymbol{t},\boldsymbol{w}} - d\Omega^-_{\boldsymbol{t},\boldsymbol{w}}\right) - \frac{1}{2\pi i}\oint_{\boldsymbol{\gamma}} \lambda \left(d\Omega^-_{\boldsymbol{t}^*,\boldsymbol{w}} - d\Omega^+_{\boldsymbol{t}^*,\boldsymbol{w}}\right)\right] \\ &= -\oint_{\boldsymbol{\gamma}} \lambda \, d\Omega_k, \end{aligned}$$

since, according to [38, Eq. (1.9)], one has

$$d\Omega^+_{\boldsymbol{z},\boldsymbol{w}} - d\Omega^-_{\boldsymbol{z},\boldsymbol{w}} = -2\pi i d\Omega_k, \quad \boldsymbol{z} \in \boldsymbol{\alpha}_k.$$

On the other hand, if $\boldsymbol{z} \to \tilde{\boldsymbol{t}}$, $\boldsymbol{z}_1 \to \boldsymbol{t} \in \boldsymbol{\alpha}_k^{\pm}$, and $\boldsymbol{z}_2 \to \boldsymbol{t}^* \in \boldsymbol{\alpha}_k^{\mp}$, then

$$\Lambda^+(\tilde{\boldsymbol{t}}) - \Lambda^-(\tilde{\boldsymbol{t}}) = \frac{1}{3}\left[-\frac{1}{2\pi i}\oint_{\boldsymbol{\gamma}} \lambda \left(d\Omega^+_{\boldsymbol{t},\boldsymbol{w}} - d\Omega^-_{\boldsymbol{t},\boldsymbol{w}}\right) - \frac{1}{2\pi i}\oint_{\boldsymbol{\gamma}} \lambda \left(d\Omega^-_{\boldsymbol{t}^*,\boldsymbol{w}} - d\Omega^+_{\boldsymbol{t}^*,\boldsymbol{w}}\right)\right] = 0.$$

Furthermore, if $\boldsymbol{z} \to \boldsymbol{t} \in \boldsymbol{\gamma}^{\pm} \setminus \bigcup_{i=1}^{g} \boldsymbol{\alpha}_i$, $\boldsymbol{z}_1 \to \boldsymbol{t}^* \in \boldsymbol{\gamma}^{\mp}$, while $\boldsymbol{z}_2$ does not approach any point on $\boldsymbol{\gamma} \cup \bigcup_{i=1}^{g} \boldsymbol{\alpha}_i$, then

$$\Lambda^+(\boldsymbol{t}) - \Lambda^-(\boldsymbol{t}) = \frac{2\lambda(\boldsymbol{t}) + \lambda(\boldsymbol{t}^*)}{3},$$

according to [38, Eq. (2.8)]. Finally, if $\boldsymbol{z} \to \tilde{\boldsymbol{t}}$, $\boldsymbol{z}_1 \to \boldsymbol{t} \in \boldsymbol{\gamma}^{\pm}$, and $\boldsymbol{z}_2 \to \boldsymbol{t}^* \in \boldsymbol{\gamma}^{\mp}$, then

$$\Lambda^+(\tilde{\boldsymbol{t}}) - \Lambda^-(\tilde{\boldsymbol{t}}) = \frac{\lambda(\boldsymbol{t}^*) - \lambda(\boldsymbol{t})}{3}.$$

Thus, if we additionally require that $\lambda(\boldsymbol{t}) = \lambda(\boldsymbol{t}^*)$, then Λ is a holomorphic function in $\mathfrak{R}_{\boldsymbol{\alpha}} \setminus \boldsymbol{\gamma}$ such that

$$\left(\Lambda^+ - \Lambda^-\right)(\boldsymbol{t}) = \begin{cases} -\oint_{\boldsymbol{\gamma}} \lambda \, d\Omega_k, & \boldsymbol{t} \in \boldsymbol{\alpha}_k \setminus \left(\boldsymbol{\gamma} \cup \boldsymbol{\alpha}_{3-k}\right), \\ \lambda(\boldsymbol{t}), & \boldsymbol{t} \in \boldsymbol{\gamma} \setminus \bigcup_{i=1}^{g} \boldsymbol{\alpha}_i. \end{cases}$$

It also can readily be verified that

$$\Lambda(\boldsymbol{z}) + \Lambda(\boldsymbol{z}_1) + \Lambda(\boldsymbol{z}_2) \equiv 0 \quad \text{on} \quad \mathfrak{R}, \tag{7.4}$$

since the cycles $\boldsymbol{\gamma}$ and $\boldsymbol{\alpha}_i$ possess projective involutions.

7.3 *Logarithmic Discontinuities*

It is known that the continuity of $\Lambda^{\pm}$, in fact, Hölder continuity, depends on the Hölder continuity of λ only locally. That is, if λ is Hölder continuous on some open subarc of $\boldsymbol{\gamma}$, so are the traces $\Lambda^{\pm}$ on this subarc irrespective of the smoothness of λ on the remaining part of $\boldsymbol{\gamma}$. Of particular importance for us are the logarithmic discontinuities at the branch points of $\mathfrak{R}$.

More precisely, let $\boldsymbol{e}$ be a branch point of $\mathfrak{R}$ and $\mathfrak{U}$ be its circular neighborhood. Given a cycle on $\mathfrak{R}$ that possesses a projective involution and passes through $\boldsymbol{e}$, denote by $\boldsymbol{\gamma}$ its part that belongs to $\mathfrak{U}$. In this case $\pi(\boldsymbol{\gamma})$ is a Jordan arc ending at $e = \pi(\boldsymbol{e})$. Recall [20, Sec. I.8.6] that

$$\frac{1}{2\pi i}\int_{\pi(\boldsymbol{\gamma})} \frac{\alpha\log(t-e)}{(t-e)^{\nu+}}\frac{dt}{t-z} = \pm\frac{\alpha e^{\pm\nu\pi i}}{2i\sin(\nu\pi)}\frac{\log(z-e)}{(z-e)^{\nu}} + \mathcal{O}\left((z-e)^{-\nu}\right) \tag{7.5}$$

as $z \to e$, where $\alpha\log(z-e)$, $\alpha \in \mathbb{R}$, and $(z-e)^{\nu}$, $\nu \neq 0$, are holomorphic outside of $\pi(\boldsymbol{\gamma})$, $\log(t-e)$ is any continuous determination of the logarithm on $\pi(\boldsymbol{\gamma})$, $(t-e)^{\nu+}$ is the trace of $(z-e)^{\nu}$ on the positive side of $\pi(\boldsymbol{\gamma})$, and the choice of the sign in $\pm$ is determined by the orientation of $\pi(\boldsymbol{\gamma})$: $+$ if $\pi(\boldsymbol{\gamma})$ is oriented away from e and $-$ if it is oriented towards e.

Assuming that $\mathfrak{R}$ has double branching at $\boldsymbol{e}$, define $u(z) := \pm(z-e)^{1/2}$, where the choice of the sign depends on whether $\boldsymbol{z}$ lies to the left $(+)$ or to the right $(-)$ of $\boldsymbol{\gamma}$. Set

$$d\mathcal{C}_{\boldsymbol{z}}(\boldsymbol{t}) := \frac{1}{2}\left(1+3\frac{u(\boldsymbol{z})}{u(\boldsymbol{t})}\right)\frac{dt}{t-z}.$$

The differential $d\mathcal{C}_{\boldsymbol{z}}$ is holomorphic in $\mathfrak{U}\setminus\{\boldsymbol{z},\boldsymbol{z}^*\}$ with residues $+2$ at $\boldsymbol{z}$ and -1 at $\boldsymbol{z}^*$, where $\boldsymbol{z}^*$ is the unique point in $\mathfrak{U}$ which is different from $\boldsymbol{z}$ and has the same natural projection. Clearly, the difference $dC_{\boldsymbol{z}} - d\mathcal{C}_{\boldsymbol{z}}$ is a holomorphic differential in $\mathfrak{U}$. Therefore, if $\lambda(\boldsymbol{t})$ is of the form $\alpha\log(t-e) + \{\text{Hölder continuous part}\}$ satisfying $\lambda(\boldsymbol{t}) = \lambda(\boldsymbol{t}^*)$, then

$$\begin{aligned}\Lambda(\boldsymbol{z}) &= \frac{1}{6\pi i}\int_{\boldsymbol{\gamma}} \alpha\log(t-e)\,d\mathcal{C}_{\boldsymbol{z}}(\boldsymbol{t}) + \mathcal{O}(1)\\ &= \frac{1}{2\pi i}\int_{\pi(\boldsymbol{\gamma})} \alpha\log(t-e)\frac{u(\boldsymbol{z})}{\sqrt{t-e}^{+}}\frac{dt}{t-z} + \mathcal{O}(1) = \pm\frac{\alpha}{2}\log(z-e) + \mathcal{O}(1) \qquad (7.6)\end{aligned}$$

as $\boldsymbol{z} \to \boldsymbol{e} \in \boldsymbol{\gamma}^{\pm}$ by (7.5) applied with $\nu = 1/2$ (observe that the second equality above is valid independently of the orientation of $\pi(\boldsymbol{\gamma})$).

Assume now that $\mathfrak{R}$ has triple branching at $\boldsymbol{e}$. Since $\boldsymbol{\gamma}$ possesses projective involution there is exactly one component of $\mathfrak{U}\setminus\boldsymbol{\gamma}$ that lies schlicht over $\pi(\mathfrak{U}\setminus\boldsymbol{\gamma})$. Orient $\boldsymbol{\gamma}$ so that this component lies to the right when $\boldsymbol{\gamma}$ is traversed in the positive direction (it is bordered by $\boldsymbol{\gamma}^-$). Define

$$d\mathcal{C}_{\boldsymbol{z}}(\boldsymbol{t}) := \left(\frac{u(\boldsymbol{z})}{u(\boldsymbol{t})} + \frac{u^2(\boldsymbol{z})}{u^2(\boldsymbol{t})}\right)\frac{dt}{t-z},$$

where $u(\boldsymbol{z})$ is equal to the lift of a fixed determination of $(z-e)^{1/3}$ to the "schlicht" component of $\mathfrak{U}$ and then is continued holomorphically to the whole $\mathfrak{U}$. Since the values of u at the points with the same natural projection differ by $e^{\pm 2\pi i/3}$, one has that $d\mathcal{C}_{\boldsymbol{z}}$ is a holomorphic differential in $\mathfrak{U}\setminus\pi^{-1}(z)$, with 3 simple poles at the elements of $\pi^{-1}(z)$ having residues $+2$ at $\boldsymbol{z}$ and -1 at the two elements of $\pi^{-1}(z)\setminus\{\boldsymbol{z}\}$. Again, $dC_{\boldsymbol{z}} - d\mathcal{C}_{\boldsymbol{z}}$ is a holomorphic differential in $\mathfrak{U}$ and therefore

$$\begin{aligned}\Lambda(\boldsymbol{z}) &= \frac{1}{6\pi i}\int_{\boldsymbol{\gamma}} \alpha\log(t-e)\,d\mathcal{C}_{\boldsymbol{z}}(\boldsymbol{t}) + \mathcal{O}(1)\\ &= \frac{\sqrt{3}i}{6\pi i}\int_{\pi(\boldsymbol{\gamma})} \alpha\log(t-e)\left(\pm e^{\pm\pi i/3}\frac{u(\boldsymbol{z})}{(t-e)^{1/3+}} \pm e^{\pm 2\pi i/3}\frac{u^2(\boldsymbol{z})}{(t-e)^{2/3+}}\right)\frac{dt}{t-z},\end{aligned}$$

where the sign $+$ is used when $\pi(\boldsymbol{\gamma})$ is oriented towards e and the sign $-$ is used if it is oriented away from e, and we used the fact that

$$\int_{\boldsymbol{\gamma}}\frac{dt}{u(\boldsymbol{t})} = \int_{\pi(\boldsymbol{\gamma})}\frac{dt}{(t-e)^{1/3-}} - \int_{\pi(\boldsymbol{\gamma})}\frac{dt}{(t-e)^{1/3+}} = \pm\sqrt{3}ie^{\pm\pi i/3}\int_{\pi(\boldsymbol{\gamma})}\frac{dt}{(t-e)^{1/3-}}$$

with the same choice of signs. Then (7.5) applied with $\nu = 1/3$ and $\nu = 2/3$ gives that

$$\begin{aligned}\Lambda(\boldsymbol{z}) &= -\frac{\alpha}{3}\log(z-e)\left(\frac{u(\boldsymbol{z})}{(z-e)^{1/3}} + \frac{u^2(\boldsymbol{z})}{(z-e)^{2/3}}\right) + \mathcal{O}(1)\\ &= \mathcal{O}(1) + \frac{\alpha}{3}\log(z-e)\begin{cases} 1, & \boldsymbol{z}\to\boldsymbol{e}\in\boldsymbol{\gamma}^+,\\ -2, & \boldsymbol{z}\to\boldsymbol{e}\in\boldsymbol{\gamma}^-,\end{cases} \qquad (7.7)\end{aligned}$$

where the determination of $(z-e)^{1/3}$ is precisely the one of $u(\boldsymbol{z})$ within the component of $\mathfrak{U}$ that lies to the right of $\boldsymbol{\gamma}$.

7.4 *Szegő Function* S_ρ

Let $\boldsymbol{\Delta}$ be the chain introduced in Theorem 6. We assume that the cycles forming $\boldsymbol{\Delta}$ and separating $\mathfrak{R}^{(0)}$ and $\mathfrak{R}^{(i)}$, $i \in \{1,2\}$, are oriented so that $\mathfrak{R}^{(0)}$ lies on the left (positive) side as each of the cycles is traversed in the positive direction, while the cycle separating $\mathfrak{R}^{(1)}$

and $\mathfrak{R}^{(2)}$ is oriented so that $\mathfrak{R}^{(1)}$ remains on the left when it is traversed in the positive direction.

To define a density whose Cauchy transform on $\boldsymbol{\Delta}$ we shall need, let us introduce auxiliary "trigonometric" weights. Namely,

$$\left\{\begin{array}{lcl} w_1(z) & := & \sqrt{z^2-a^2}, \\ w_2(z) & := & \sqrt{(z^2-1)(z^2-b^2)(z^2+c^2)}, \end{array}\right. \tag{7.8}$$

in Case I with branch cuts along Δ_1, $\Delta_2 \cup \Delta_0$, respectively (all are positive for positive reals large enough), and

$$\left\{\begin{array}{lcl} w_1(z) & := & \sqrt{z^2-b^2}, \\ w_2(z) & := & \sqrt{(z^2-1)(z^2-a^2)}, \end{array}\right. \tag{7.9}$$

in Cases II and III with branch cuts along Δ_1 and Δ_2, respectively (all are positive for positive reals large enough). We set

$$\lambda_\rho(\mathbf{t}) := \left\{\begin{array}{ll} -\log\big(\rho_1 w_1^+\big)(t), & t \in \Delta_1^\circ, \\ -\log\big(-\rho_2 w_2^+\big)(t), & t \in \Delta_{21}^\circ, \\ -\log\big(\rho_2 w_2^+\big)(t), & t \in \Delta_{22}^\circ, \\ -\log\big(\rho_2 w_2^+/\rho_1 w_1\big)(t), & t \in \Delta_0^\circ, \end{array}\right. \quad \mathbf{t} \in \boldsymbol{\Delta}, \tag{7.10}$$

where we choose continuous branches of the logarithms, which is possible as the functions ρ_i and the trigonometric weights are non-vanishing except at the endpoints. Put

$$S_\rho(\mathbf{z}) := \exp\big\{\Lambda_\rho(\mathbf{z})\big\}, \quad \vec{c}_\rho := -\frac{1}{2\pi i}\oint_{\boldsymbol{\Delta}} \lambda_\rho \, d\vec{\Omega}. \tag{7.11}$$

Then S_ρ is a holomorphic and non-vanishing function on $\mathfrak{R}_{\boldsymbol{\alpha}} \setminus \boldsymbol{\Delta}$ with continuous traces except at the branch points that satisfy

$$S_\rho^+ = S_\rho^- \left\{\begin{array}{ll} \exp\big\{2\pi i \big(\vec{c}_\rho\big)_k\big\} & \text{on} \quad \boldsymbol{\alpha}_k \\ \exp\{\lambda_\rho\} & \text{on} \quad \boldsymbol{\Delta}. \end{array}\right. \tag{7.12}$$

Moreover, S_ρ satisfies (2.10) with Φ replaced by S_ρ as follows from (7.4), and, excluding the case $a = b = 1/\sqrt{2}$, one has

$$\left\{\begin{array}{lll} \big|S_\rho^{(0)}(z)\big| \sim |z-e|^{-1/4} & \text{as} & z \to e \in \{\pm 1, \pm a, \pm b\}, \\ \big|S_\rho^{(1)}(z)\big| \sim |z-e|^{1/4} & \text{as} & z \to e \in \{\pm e_1\}, \\ \big|S_\rho^{(1)}(z)\big| \sim |z-e|^{-1/4} & \text{as} & z \to e \in \{\pm ic\}, \\ \big|S_\rho^{(2)}(z)\big| \sim |z-e|^{1/4} & \text{as} & z \to e \in \{\pm 1, \pm e_2, \pm ic\}, \end{array}\right. \tag{7.13}$$

by (7.6), where $e_1 = a$ and $e_2 = b$ in Case I while $e_1 = b$ and $e_2 = a$ in Cases II and III, and the points $\pm ic$ appear only in Case I. When $e_1 = e_2 = 1/\sqrt{2}$, we need to use (7.7) instead of (7.6). Now there are two cycles that pass through a branch point: one that separates $\mathfrak{R}^{(0)}$ and $\mathfrak{R}^{(1)}$ ($\mathfrak{R}^{(1)}$ lies to the right of this cycle), and one that separates $\mathfrak{R}^{(0)}$ and $\mathfrak{R}^{(2)}$ ($\mathfrak{R}^{(2)}$ lies to the right of this cycle). Combing the contributions from the integrals over both cycles we get that

$$\left\{\begin{array}{lll} \big|S_\rho^{(0)}(z)\big| \sim |z-e|^{-1/3} & \text{as} & z \to e \in \big\{\pm 1/\sqrt{2}\big\}, \\ \big|S_\rho^{(i)}(z)\big| \sim |z-e|^{1/6} & \text{as} & z \to e \in \big\{\pm 1/\sqrt{2}\big\}, \quad i \in \{1,2\}. \end{array}\right. \tag{7.14}$$

7.5 *Riemann Theta Function*

The theta function associated with $\mathbf{B}$ is an entire transcendental function of g complex variables defined by

$$\theta\left(\vec{u}\right) := \sum_{\vec{n}\in\mathbb{Z}^g} \exp\left\{\pi i \vec{n}^{\mathsf{T}}\mathbf{B}\vec{n} + 2\pi i \vec{n}^{\mathsf{T}}\vec{u}\right\}, \quad \vec{u}\in\mathbb{C}^g.$$

As shown by Riemann, the symmetry of $\mathbf{B}$ and positive definiteness of its imaginary part ensures the convergence of the series for any $\vec{u}$. It is known that

$$\theta\left(\vec{u}\right) = 0 \quad \Leftrightarrow \quad \vec{u} \equiv \left\{\begin{array}{rl} \vec{\Omega}\left(\boldsymbol{w}\right)+\vec{K}, & g=2, \\ \vec{K}, & g=1, \end{array}\right. \quad \left(\text{mod periods } d\vec{\Omega}\right) \tag{7.15}$$

for some $\boldsymbol{w}\in\mathfrak{R}$, where the equivalence $\equiv$ was defined in (3.3) and $\vec{K}$ is the vector of Riemann constants defined by

$$\left\{\begin{array}{lcll} \left(\vec{K}\right)_k & := & \left([\mathbf{B}]_{kk}-1\right)/2 - \oint_{\boldsymbol{\alpha}_{3-k}} \Omega_k^- d\Omega_{3-k}, & g=2, \\ \vec{K} & := & \left(\mathbf{B}-1\right)/2, & g=1. \end{array}\right.$$

Let $\mathcal{D}$ be an integral divisor of order g. Then $\theta\big(\vec{\Omega}(\boldsymbol{z})-\vec{\Omega}(\mathcal{D})-\vec{K}\big)$ is a multi-valued holomorphic function on $\mathfrak{R}$ if $\mathcal{D}$ is not special and is identically zero otherwise. Indeed, in the later case $\Omega(\mathcal{D}) = \Omega(\boldsymbol{z}+\hat{\boldsymbol{z}})+\vec{j}_z+\mathbf{B}\vec{m}_z$, $\vec{j}_z,\vec{m}_z\in\mathbb{Z}^g$ and therefore

$$\theta\left(\vec{\Omega}(\boldsymbol{z})-\vec{\Omega}(\mathcal{D})-\vec{K}\right) = \theta\left(-\vec{\Omega}(\hat{\boldsymbol{z}})-\vec{K}\right)e^{-\pi i\vec{m}_z^{\mathsf{T}}\mathbf{B}\vec{m}_z-2\pi i\vec{m}_z^{\mathsf{T}}\left(\vec{\Omega}(\hat{\boldsymbol{z}})+\vec{K}\right)} = 0$$

by (7.15), where we used the fact $\theta(-\vec{u}) = \theta(\vec{u})$ and the periodicity property of theta functions:

$$\theta\left(\vec{u}+\vec{j}+\mathbf{B}\vec{m}\right) = \exp\left\{-\pi i\vec{m}^{\mathsf{T}}\mathbf{B}\vec{m}-2\pi i\vec{m}^{\mathsf{T}}\vec{u}\right\}\theta\left(\vec{u}\right), \quad \vec{j},\vec{m}\in\mathbb{Z}^g. \tag{7.16}$$

Set $\vec{v}_k := \vec{\Omega}\big(\infty^{(k)}-\infty^{(0)}\big)$, $k\in\{0,1,2\}$, and define

$$\Theta_{n,k}(\boldsymbol{z}) := \frac{\theta\left(\vec{\Omega}(\boldsymbol{z})-\vec{\Omega}\big(g\infty^{(2)}\big)-\vec{K}-\vec{v}_k-\vec{c}_\rho-\vec{x}_n-\mathbf{B}\vec{y}_n\right)}{\theta\left(\vec{\Omega}(\boldsymbol{z})-\vec{\Omega}\big(g\infty^{(2)}\big)-\vec{K}\right)} \tag{7.17}$$

(recall that $2\infty^{(2)}$ is not a special divisor, see (7.2) and after, and therefore $\Theta_{n,k}$ is always well defined), where $\vec{x}_n,\vec{y}_n\in[0,1)^g$ are such that

$$\vec{x}_n+\mathbf{B}\vec{y}_n \equiv n\left(\vec{\omega}+\mathbf{B}\vec{\tau}\right) \quad \left(\text{mod periods } d\vec{\Omega}\right). \tag{7.18}$$

If the numerator is not identically zero, $\Theta_{n,k}$ is a multiplicatively multi-valued meromorphic function on $\mathfrak{R}$ with g simple poles at $\infty^{(2)}$, g zeros that we shall describe by an integral divisor $\mathcal{D}_{n,k}$, and otherwise non-vanishing and finite (it is also possible that zeros could cancel poles). Moreover, it follows from (3.1) and (7.16) that $\Theta_{n,k}$ is meromorphic and single-valued in $\mathfrak{R}_{\boldsymbol{\alpha}}$ and

$$\Theta_{n,k}^+ = \Theta_{n,k}^- \exp\left\{-2\pi i\left(\vec{v}_k+\vec{c}_\rho+\vec{x}_n+\mathbf{B}\vec{y}_n\right)_i\right\} \qquad \text{on} \quad \boldsymbol{\alpha}_i. \tag{7.19}$$

Together with the functions $\Theta_{n,k}$ we shall need two more auxiliary theta functions. We set

$$\Theta_k(\boldsymbol{z}) = \frac{\theta\left(\vec{\Omega}(\boldsymbol{z})-\vec{\Omega}\big(\infty^{(0)}+(g-1)\boldsymbol{w}\big)-\vec{K}\right)}{\theta\left(\vec{\Omega}(\boldsymbol{z})-\vec{\Omega}\big(\infty^{(k)}+(g-1)\boldsymbol{w}\big)-\vec{K}\right)}, \quad k\in\{0,1,2\},$$

for any fixed $\boldsymbol{w}$ such that $\boldsymbol{w}\neq\hat{\infty}^{(k)}$ for all $k\in\{0,1,2\}$. Clearly, $\Theta_0\equiv 1$ and Θ_i, $i\in\{1,2\}$, is a meromorphic function in $\mathfrak{R}_{\boldsymbol{\alpha}}$, with a simple zero at $\infty^{(0)}$, a simple pole at $\infty^{(i)}$, and otherwise non-vanishing and finite. Moreover, its traces on $\boldsymbol{\alpha}_k$ satisfy

$$\Theta_i^+ = \Theta_i^- \exp\left\{2\pi i\left(\vec{v}_i\right)_k\right\} \qquad \text{on} \quad \boldsymbol{\alpha}_k. \tag{7.20}$$

7.6 *Jacobi Inversion Problem*

It follows from (7.15) and (7.18) that the divisor $\mathcal{D}_{n,k}$ is a solution of the Jacobi inversion problem

$$\vec{\Omega}(\mathcal{D}_{n,k}) \equiv \vec{\Omega}\big(g\infty^{(2)}\big) + \vec{v}_k + \vec{c}_\rho + n(\vec{\omega} + \mathbf{B}\vec{\tau}) \quad \Big(\text{mod periods } d\vec{\Omega}\Big). \tag{7.21}$$

Clearly, $\mathcal{D}_{n,0}$ are precisely the divisors $\mathcal{D}_n$ defined in (3.2).

As we already mentioned after (3.2), any Jacobi inversion problem is uniquely solvable on surfaces of genus 1. Thus, $\mathcal{D}_{n,k}$ are well defined in this case. Since

$$\vec{\Omega}(\mathcal{D}_{n,k}) \equiv \vec{\Omega}(\mathcal{D}_{n-1,k}) + \vec{\omega} + \mathbf{B}\vec{\tau} \quad \Big(\text{mod periods } d\vec{\Omega}\Big), \tag{7.22}$$

Proposition 2 and the unique solvability property imply that

$$\mathcal{D}_{2m,k} = \mathcal{D}_{0,k} \neq \mathcal{D}_{1,k} = \mathcal{D}_{2m+1,k}$$

for all $m \geqslant 0$. This finishes the proof of Proposition 4. Observe also that

$$\vec{\Omega}(\mathcal{D}_{n,k}) \equiv \vec{\Omega}\big(\mathcal{D}_{n,j} - \infty^{(j)} + \infty^{(k)}\big) \quad \Big(\text{mod periods } d\vec{\Omega}\Big). \tag{7.23}$$

The latter equivalence together with the unique solvability property imply that

$$\mathcal{D}_{n,j} = \infty^{(j)} \quad \text{for some} \quad j \in \{0,1,2\} \quad \Rightarrow \quad \mathcal{D}_{n,k} = \infty^{(k)} \quad \text{for all} \quad k \in \{0,1,2\}.$$

Hence, if $\mathcal{D}_{n,0} \neq \infty^{(0)}$, then $\mathcal{D}_{n,i} \neq \infty^{(i)}$, $i \in \{1,2\}$, which will be important in what follows.

As to Proposition 5, observe that its first claim follows from (7.22) and Proposition 2 as $\vec{\Omega}$ assumes equivalent values at special divisors by Abel's theorem (7.3). To prove the second claim, assume to the contrary that all the limit points of $\{\mathcal{D}_{n,0}\}_{n\in\mathbb{N}}$ are either special or of the form $\infty^{(0)} + \boldsymbol{w}$ for some $\boldsymbol{w} \in \mathfrak{R}$. Using compactness, we always can select a subsequence $\mathbb{N}_1$ such that

$$\mathcal{D}_{n+j,0} \to \mathcal{D}^j \quad \text{as} \quad \mathbb{N}_1 \ni n \to \infty$$

for some divisors $\mathcal{D}^j$ simultaneously for all $j \in \{0,1,2,3\}$. According to our assumption, one has

$$\vec{\Omega}(\mathcal{D}^j) \equiv \vec{\Omega}\big(\infty^{(0)} + \boldsymbol{w}_j\big), \tag{7.24}$$

where $\boldsymbol{w}_j = \hat{\infty}^{(0)}$ when $\mathcal{D}^j$ is special. Observe also that continuity of $\vec{\Omega}$ and (7.22) imply that

$$\vec{\Omega}(\mathcal{D}^{j+1}) \equiv \vec{\Omega}(\mathcal{D}^j) + \vec{\omega} + \mathbf{B}\vec{\tau} \quad \Big(\text{mod periods } d\vec{\Omega}\Big) \tag{7.25}$$

for $j \in \{0,1,2\}$. By combining (7.25) for different j and then recalling (7.24), we deduce that

$$\vec{\Omega}(2\boldsymbol{w}_j) \equiv \vec{\Omega}\big(\boldsymbol{w}_{j+1} + \boldsymbol{w}_{j-1}\big) \quad \Big(\text{mod periods } d\vec{\Omega}\Big),$$

$j \in \{1,2\}$. The latter equivalence and Abel's theorem imply that $2\boldsymbol{w}_1$ and $\boldsymbol{w}_3 + \boldsymbol{w}_1$ are special divisors, and therefore necessarily $\boldsymbol{w}_3 = \boldsymbol{w}_1$. The above conclusion and (7.25) imply that

$$2\vec{\omega} + 2\mathbf{B}\vec{\tau} \equiv \vec{0} \quad \Big(\text{mod periods } d\vec{\Omega}\Big),$$

which is impossible since $2\vec{\omega} = (2\omega, 4(1-\omega))$ and $2\omega \in (1,2)$ by Proposition 2. This contradiction proves the second claim of Proposition 5.

Finally, observe that the subsequence $\mathbb{N}_*$ is such that no limit point of $\{\mathcal{D}_{n,i}\}_{n\in\mathbb{N}_*}$ is special or of the form $\infty^{(i)} + \boldsymbol{w}$ for $i \in \{1,2\}$. Indeed, otherwise there would exist a limit point $\mathcal{D}$ of one those sequences such that

$$\vec{\Omega}(\mathcal{D}) \equiv \vec{\Omega}\big(\infty^{(i)} + \boldsymbol{w}\big),$$

where $\boldsymbol{w} = \hat{\infty}^{(i)}$ if $\mathcal{D}$ is special. Choose a limit point $\mathcal{D}_*$ of $\{\mathcal{D}_{n,0}\}$ along the same subsequence. The continuity of $\vec{\Omega}$ and (7.23) then would imply that

$$\vec{\Omega}(\mathcal{D}_*) \equiv \vec{\Omega}\big(\mathcal{D} - \infty^{(i)} + \infty^{(0)}\big) \equiv \vec{\Omega}\big(\infty^{(0)} + \boldsymbol{w}\big) \quad \Big(\text{mod periods } d\vec{\Omega}\Big),$$

which means that either $\mathcal{D}_*$ is special or contains $\infty^{(0)}$. As both options are impossible by the choice of $\mathbb{N}_*$, such a limit point $\mathcal{D}$ does not exist.

7.7 *Nuttall-Szegő Functions*

Finally, we are ready to prove Theorem 6. Let $\vec{y} \in \mathbb{R}^g$. Then it follows from (3.1) that

$$S_{\vec{y}}(z) := \exp\big\{-2\pi i \vec{y}^{\mathsf{T}} \vec{\Omega}(z)\big\}, \quad z \in \mathfrak{R}_{\alpha,\beta},$$

is a holomorphic function on $\mathfrak{R}_{\alpha,\beta}$ with continuous traces that satisfy

$$S_{\vec{y}}^+ = S_{\vec{y}}^- \begin{cases} \exp\big\{2\pi i(\mathbf{B}\vec{y})_i\big\} & \text{on} \quad \boldsymbol{\alpha}_i \\ \exp\big\{-2\pi i(\vec{y})_i\big\} & \text{on} \quad \boldsymbol{\beta}_i. \end{cases} \tag{7.26}$$

Moreover, (7.4) implies that (2.10) holds with Φ replaced by $S_{\vec{y}}$. Finally, set

$$W\big(z^{(0)}\big) \equiv 1 \quad \text{and} \quad W\big(z^{(i)}\big) = w_i(z), \quad i \in \{1, 2\},$$

where the functions w_1 and w_2 are defined by (7.8) or (7.9), depending on the considered case. The Nuttall-Szegő functions we are looking for are defined by

$$\Psi_{n,k} := \Phi^n S_\rho S_{\vec{y}_n} \Theta_{n,k} \Theta_k W^{-1}, \tag{7.27}$$

where $\vec{y}_n$ was defined in (7.18) and we assume n is such that the corresponding Jacobi inversion problem (7.21) is uniquely solvable. Indeed, it can readily be checked, using (2.11), (7.12), (7.18), (7.19), (7.20), and (7.26), that each $\Psi_{n,k}$ is holomorphic in $\mathfrak{R} \setminus \boldsymbol{\Delta}$ and its traces satisfy

$$(W\Psi_{n,k})^+ = (W\Psi_{n,k})^- \exp\{\lambda_\rho\} \quad \text{on} \quad \boldsymbol{\Delta}.$$

Using the definition of W and (7.10), we see that the pullbacks of $\Psi_{n,k}$ solve the boundary value problem (3.6). Further, the functions $\Psi_{n,k}$ have the local behavior around the branch points of $\mathfrak{R}$ as stated in (3.5) by the very definition of W and (7.13) or (7.14). Finally, the zero/pole multi-set of $\Psi_{n,k}$ in $\mathfrak{R} \setminus \boldsymbol{\Delta}$ is described by the divisor

$$\mathcal{D}_{n,k} + (n+1)\Big(\infty^{(1)} + \infty^{(2)}\Big) - \infty^{(k)} - (2n-1)\infty^{(0)} \tag{7.28}$$

as follows from the properties of Φ^n, $\Theta_{n,k}$, Θ_k, and W. In particular, the functions satisfying conditions of Theorem 6 are given by $\Psi_n := \Psi_{n,0}$.

It only remains to show the uniqueness of $\Psi_{n,k}$. To this end, consider $\Psi_{n,k}/\Psi$, where Ψ satisfies (3.5), (3.6), and (7.28) with $\mathcal{D}_{n,k}$ replaced by any other integral divisor, say $\mathcal{D}$. Then the analytic continuation property implies that $\Psi_{n,k}/\Psi$ is a rational function on $\mathfrak{R}$ whose divisor is given by $\mathcal{D}_{n,k} - \mathcal{D}$. As $\mathcal{D}_{n,k}$ is not special, $\mathcal{D} = \mathcal{D}_{n,k}$, that is $\Psi_{n,k}/\Psi$ is a constant.

7.8 *Auxiliary Observation*

In Section 9, we shall need the following observation. Assuming we are in Case II, let $\mathcal{D}_{n,k}(\rho)$ be the solution of (7.21) for the weights ρ_1 and ρ_2 and $\mathcal{D}_{n,k}(1/\rho)$ be the solution of (7.21) for the weights $1/\rho_1$ and $1/\rho_2$. Then it can easily be seen from (7.21), (7.10), and (2.15) that

$$\vec{\Omega}\big(\mathcal{D}_{n,k}(\rho) + \mathcal{D}_{n,k}(1/\rho)\big) \equiv 2\vec{\Omega}\big(\infty^{(2)}\big) + 2\vec{v}_k + 2\vec{c}_1 \equiv 2\vec{\Omega}(\mathcal{D}_{n,k}(1)).$$

Moreover, it also follows from (2.15) and (3.6) that $\big(S_1 S_{\vec{y}_n}\Theta_{n,k}\Theta_k\big)^2$ is a rational function on $\mathfrak{R}$ with the divisor equal to the sum of the divisors (7.1) and $2\mathcal{D}_{n,k}(1) - 2\infty^{(k)}$. As the divisor (7.1) is a divisor of a rational function, we get from Abel's theorem (7.3) that

$$\vec{\Omega}\big(\mathcal{D}_{n,k}(\rho) + \mathcal{D}_{n,k}(1/\rho)\big) \equiv 2\vec{\Omega}\big(\infty^{(k)}\big).$$

In particular, it follows from the unique solvability of the Jacobi inversion problem that

$$\mathcal{D}_{n,k}(\rho) = \infty^{(k)} \quad \Leftrightarrow \quad \mathcal{D}_{n,k}(1/\rho) = \infty^{(k)}. \tag{7.29}$$

That is, $n \in \mathbb{N}_*(\rho)$ if and only if $n \in \mathbb{N}_*(1/\rho)$.

7.9 *Asymptotic Behavior*

Below we prove Theorem 7. In fact, we shall show that a more general statement is true. Given $\mathbb{N}_*$ and $\varepsilon > 0$ small, there exists a constant $1 < C_\varepsilon(\mathbb{N}_*) < \infty$ such that

$$\begin{cases} |\Psi_{n,k}| \leqslant C_\varepsilon(\mathbb{N}_*)\,|\Phi|^n & \text{in} \quad \mathfrak{R}_\varepsilon, \\ |\Psi_{n,k}| \geqslant C_\varepsilon(\mathbb{N}_*)^{-1}\,|\Phi|^n & \text{in} \quad \mathfrak{U}_\varepsilon^{(k)}, \end{cases} \tag{7.30}$$

for all $n \in \mathbb{N}_*$ large, where $\mathfrak{U}_\varepsilon^{(k)} := \mathfrak{R}^{(k)} \cap \pi^{-1}\big(\{|z| > 1/\varepsilon\}\big)$.

It follows from the continuity of the boundary values of S_ρ as well as from (7.13) that $|S_\rho|$ is bounded from above and away from zero in $\mathfrak{R}_\varepsilon$ (that is, including the boundary values on $\boldsymbol{\Delta}$ and the $\boldsymbol{\alpha}$-cycles). Moreover, since the image of $\mathfrak{R}_{\alpha,\beta}$ under $\vec{\Omega}$ is bounded and $\vec{y}_n \in [0,1)^g$ by the very definition, see (7.18), the moduli $|S_{\vec{y}_n}|$ are uniformly bounded from above and away from zero. Thus, we only need to estimate the function $\Theta_{n,k}\Theta_k W^{-1}$.

It follows from (7.28) that the zero/pole multi-set of $\Theta_{n,k}\Theta_k W^{-1}$ in $\mathfrak{R}_{\boldsymbol{\alpha}} \setminus \boldsymbol{\Delta}$ is equal to $\mathcal{D}_{n,k} + \infty^{(0)} + \infty^{(1)} + \infty^{(2)} - \infty^{(k)}$ and therefore these functions are holomorphic there as well as non-vanishing in $\mathfrak{U}_\varepsilon^{(k)}$ for all $\varepsilon > 0$ small and n large by the very choice of $\mathbb{N}_*$. Hence,

$$\begin{cases} \big|\Theta_{n,k}\Theta_k W^{-1}\big| \leqslant C_{n,\varepsilon}(\mathbb{N}_*) & \text{in} \quad \mathfrak{R}_\varepsilon, \\ \big|\Theta_{n,k}\Theta_k W^{-1}\big| \geqslant C_{n,\varepsilon}(\mathbb{N}_*)^{-1} & \text{in} \quad \mathfrak{U}_\varepsilon^{(k)}. \end{cases} \tag{7.31}$$

Thus, if we show that $\big\{\Theta_{n,k}\Theta_k W^{-1}\big\}$ is a normal family and every limit point satisfies the estimates as in (7.31), a standard compactness argument will finish the proof of (7.30). The only varying part of this family is given by

$$\theta\left(\vec{\Omega}(z) - \vec{\Omega}\big(g\infty^{(2)}\big) - \vec{K} - \vec{v}_k - \vec{c}_\rho - \vec{x}_n - \mathbf{B}\vec{y}_n\right). \tag{7.32}$$

Boundedness of its image follows from the continuity of $\theta(\cdot)$, boundedness of the image of $\vec{\Omega}(z)$ for $z \in \mathfrak{R}_{\alpha,\beta}$, and the fact that $\vec{x}_n, \vec{y}_n \in [0,1)^g$. Thus, $\big\{\Theta_{n,k}\Theta_k W^{-1}\big\}$ is a normal family and its elements are indexed by pairs $(\vec{x}_n, \vec{y}_n) \in [0,1)^{2g}$. The continuity of $\theta(\cdot)$ and (7.17) imply that any limit point of the functions in (7.32) has the same form with $(\vec{x}_n, \vec{y}_n)$ replaced by a limit point $(\vec{x}, \vec{y}) \in [0,1]^{2g}$. Denote by $\mathcal{D}$ the integral divisor of order g describing the zeros of this limit point. Then

$$\vec{\Omega}(\mathcal{D}) \equiv \vec{\Omega}\big(g\infty^{(2)}\big) + \vec{v}_k + \vec{c}_\rho + \vec{x} + \mathbf{B}\vec{y} \quad \left(\text{mod periods } d\vec{\Omega}\right).$$

The continuity of $\vec{\Omega}$ implies that the right-hand side of the equivalence above is a limit point of the right-hand sides in (7.21). By the definition of $\mathbb{N}_*$, it determines $\mathcal{D}$ uniquely as it is a limit point of $\{\mathcal{D}_{n,k}\}_{n\in\mathbb{N}_*}$. Moreover, all such limit points are uniformly bounded away from containing $\infty^{(k)}$ and therefore from containing an element from $\mathfrak{U}_\varepsilon^{(k)}$ for all $\varepsilon > 0$ small enough, which is sufficient to get the required lower estimate.

8 RIEMANN-HILBERT ANALYSIS: CASE I

8.1 Global Lenses

Set

$$\mathbf{G}_1(u) := \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & u & 1 \end{pmatrix} \quad \text{and} \quad \mathbf{G}_2(v) := \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & v \\ 0 & 0 & 1 \end{pmatrix}. \tag{8.1}$$

Observe that $\mathbf{G}_i(u)^{-1} = \mathbf{G}_i(-u)$, $i \in \{1, 2\}$. Moreover, with J as in (5.5),

$$\begin{cases} \mathbf{G}_1^{-1}(u)\mathbf{J}(x,y)\mathbf{G}_1(u) = \mathbf{J}(x+uy, y) \\ \mathbf{G}_2^{-1}(v)\mathbf{J}(x,y)\mathbf{G}_2(v) = \mathbf{J}(x, y+vx). \end{cases} \tag{8.2}$$

That is, conjugating $\mathbf{J}$ by $\mathbf{G}_i$ allows one to modify the i-th variable of the matrix $\mathbf{J}$ using the other variable.

Let, as before, $\pm ic$, $c > 0$, be the projections of the branch points of $\mathfrak{R}$ and Γ be the cut along which the sheets $\mathfrak{R}^{(1)}$ and $\mathfrak{R}^{(2)}$ are glued to each other. Pick arcs $\Delta_{01\pm}$ and Δ_{02}, all oriented from $-ic$ to ic, as in Figure 12. These arcs delimit three bounded domains that we label from left to right as O_0, O_1, and O_2.

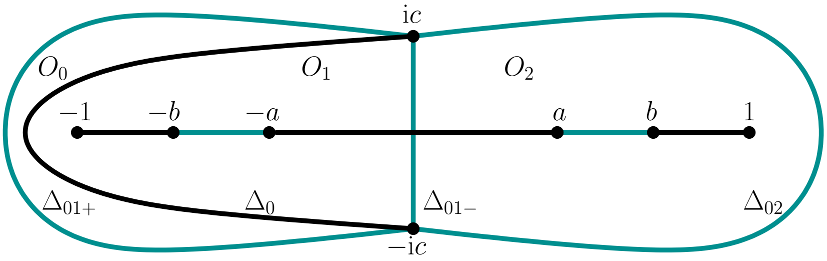

FIGURE 12. The lens Σ_S and the domains O_0, O_1, and O_2.

Set $\mathbf{S} := \mathbf{Y}$ outside of the closure of $O_0 \cup O_1 \cup O_2$ and inside put

$$\mathbf{S} := \mathbf{Y} \begin{cases} \mathbf{G}_1(-\rho_1/\rho_2) & \text{in} \quad O_0, \\ \mathbf{G}_2(-\rho_2/\rho_1)\mathbf{G}_1(\rho_1/\rho_2) & \text{in} \quad O_1, \\ \mathbf{G}_2(-\rho_2/\rho_1) & \text{in} \quad O_2, \end{cases} \tag{8.3}$$

where the ρ_i are the weight functions in (4.1). This way $\mathbf{S}$ has jumps on $\Delta_{01\pm}$, Δ_{02}, and Δ_0. In particular, the jump on Δ_0 is equal to

$$J_0 := \mathbf{G}_1(-\rho_1/\rho_2)\mathbf{G}_2(\rho_2/\rho_1)\mathbf{G}_1(-\rho_1/\rho_2) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & \rho_2/\rho_1 \\ 0 & -\rho_1/\rho_2 & 0 \end{pmatrix}.$$

For brevity, let us write

$$\rho_2^*(z) := \begin{cases} \rho_2(z), & \mathsf{Re}(z) > 0, \\ -\rho_2(z), & \mathsf{Re}(z) < 0. \end{cases} \tag{8.4}$$

Put $\Sigma_S := [-1, 1] \cup \Delta_{01+} \cup \Delta_{01-} \cup \Delta_{02} \cup \Delta_0$. Then $\mathbf{S}$ solves RHP-$\mathbf{S}$:

(a) $\mathbf{S}$ is analytic in $\mathbb{C} \setminus \Sigma_S$ and $\lim_{z\to\infty} \mathbf{S}(z)\mathsf{diag}\left(z^{-2n}, z^n, z^n\right) = \mathbf{I}$;

(b) $\mathbf{S}$ has continuous traces on $\Sigma_{\mathbf{S}}^\circ := \Sigma_{\mathbf{S}} \setminus \{\pm 1, \pm a, \pm ic\}$ that satisfy

$$\mathbf{S}_+ = \mathbf{S}_- \begin{cases} \mathbf{J}(0, \rho_2^*) & \text{on} \quad (-1,-a) \cup (a,1), \\ \mathbf{J}(\rho_1, 0) & \text{on} \quad (-a,a) \setminus \{0\}, \\ \mathbf{J}_0, & \text{on} \quad \Delta_0, \\ \mathbf{G}_1(\rho_1/\rho_2) & \text{on} \quad \Delta_{01\pm}, \\ \mathbf{G}_2(-\rho_2/\rho_1) & \text{on} \quad \Delta_{02}; \end{cases}$$

(c) $\mathbf{S}$ satisfies RHP-$\mathbf{Y}$(c) (see Section 5) with $[-1,1]$ replaced by $\Sigma_{\mathbf{S}}$.

If RHP-$\mathbf{S}$ is solvable, then so is RHP-$\mathbf{Y}$, and the solutions are connected via (8.3).

8.2 *Local Lenses*

For the next step we introduce additional arcs $\Delta_{1\pm}$ and systems of two arcs $\Delta_{2\pm}$ as on Figure 13, all oriented from left to right. Denote further by $O_{1\pm}$ the domains bounded by

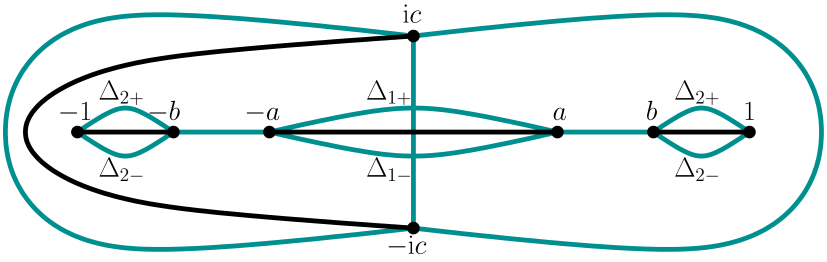

FIGURE 13. The lens $\Sigma_{\mathbf{Z}}$: specifically, the arcs $\Delta_{1\pm}$ and systems of arcs $\Delta_{2\pm}$. The black curves constitute the system $\Sigma_{\mathbf{N}}$.

$(-a,a)$ and the arcs $\Delta_{1\pm}$, respectively, and by $O_{2\pm}$ the open sets bounded by $\Delta_{2\pm}$ and $(-1,-b) \cup (b,1)$. Set

$$\mathbf{Z} := \mathbf{S}\mathbf{L}_i^{\mp 1} \quad \text{in} \quad O_{i\pm}, \tag{8.5}$$

$i \in \{1,2\}$, where

$$\mathbf{L}_1 := \begin{pmatrix} 1 & 0 & 0 \\ 1/\rho_1 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad \mathbf{L}_2 := \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1/\rho_2^* & 0 & 1 \end{pmatrix}. \tag{8.6}$$

It can readily be checked that $\mathbf{Z}_+ = \mathbf{Z}_- \mathbf{J}_i$ on Δ_i, $i \in \{1,2\}$, see (2.8), where

$$\mathbf{J}_1 := \begin{pmatrix} 0 & \rho_1 & 0 \\ -1/\rho_1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad \mathbf{J}_2 := \begin{pmatrix} 0 & 0 & \rho_2^* \\ 0 & 1 & 0 \\ -1/\rho_2^* & 0 & 0 \end{pmatrix}. \tag{8.7}$$

Put $\Sigma_{\mathbf{Z}} := \Sigma_{\mathbf{S}} \cup \Delta_{1+} \cup \Delta_{1-} \cup \Delta_{2+} \cup \Delta_{2-}$. Then $\mathbf{Z}$ solves RHP-$\mathbf{Z}$:

(a) $\mathbf{Z}$ is analytic in $\mathbb{C} \setminus \Sigma_{\mathbf{Z}}$ and $\lim_{z\to\infty} \mathbf{Z}(z)\operatorname{diag}\left(z^{2n}, z^{-n}, z^{-n}\right) = \mathbf{I}$;

(b) $\mathbf{Z}$ has continuous traces on each side of $\Sigma_{\mathbf{Z}}^\circ := \Sigma_{\mathbf{Z}} \setminus \{\pm 1, \pm a, \pm b, \pm ic\}$ that satisfy

$$\mathbf{Z}_+ = \mathbf{Z}_- \begin{cases} \mathbf{J}_k & \text{on} \quad \Delta_k^\circ \setminus \{0\}, \quad k \in \{0,1,2\}, \\ \mathbf{J}_{\mathbf{Z}} & \text{on} \quad \Sigma_{\mathbf{Z}}^\circ \setminus (\Delta_0 \cup \Delta_1 \cup \Delta_2), \end{cases}$$

where

$$\mathbf{J}_{\mathbf{Z}} := \begin{cases} \mathbf{J}(0, \rho_2^*) & \text{on} \quad (-b,-a) \cup (a,b), \\ \mathbf{G}_1(\rho_1/\rho_2) & \text{on} \quad \Delta_{01\pm}, \\ \mathbf{G}_2(-\rho_2/\rho_1) & \text{on} \quad \Delta_{02}, \\ \mathbf{L}_i & \text{on} \quad \Delta_{i\pm}, \quad i \in \{1,2\}; \end{cases} \tag{8.8}$$

(c) $\mathbf{Z}$ satisfies RHP-$\mathbf{S}$(c) with $\Sigma_\mathbf{S}$ replaced by $\Sigma_\mathbf{Z}$.

As before, if RHP-$\mathbf{Z}$ is solvable, then so is RHP-$\mathbf{S}$, and the solutions are connected via (8.5).

8.3 *Global Parametrix*

Let $\Sigma_\mathbf{N} := \Delta_0 \cup \Delta_1 \cup \Delta_2$, see Figure 13. In this section we are seeking the solution of the following Riemann-Hilbert problem (RHP-$\mathbf{N}$):

(a) $\mathbf{N}$ is analytic in $\mathbb{C}\setminus\Sigma_\mathbf{N}$ and $\lim_{z\to\infty}\mathbf{N}(z)\mathsf{diag}\left(z^{-2n},z^n,z^n\right)=\mathbf{I}$;

(b) $\mathbf{N}$ has continuous traces on each side of $\Sigma_\mathbf{N}\setminus\{\pm1,\pm a,\pm b,\pm ic\}$ that satisfy $\mathbf{N}_+ = \mathbf{N}_-\mathbf{J}_k$ on Δ_k°, $k\in\{0,1,2\}$.

We solve RHP-$\mathbf{N}$ only along the subsequence $\mathbb{N}_*$ defined in Proposition 5. Let $\Psi_{n,k}$ be the n-th Nuttall-Szegő functions constructed in (7.27). As the functions $\Psi_{n,k}$ satisfy (3.6) with the zero/pole sets described by (7.28), it readily follows that a solution of RHP-$\mathbf{N}$ is given by

$$\mathbf{N} := \mathbf{C}_n \begin{pmatrix} \Psi_{n,0}^{(0)} & \Psi_{n,0}^{(1)} & \Psi_{n,0}^{(2)} \\ \Psi_{n,1}^{(0)} & \Psi_{n,1}^{(1)} & \Psi_{n,1}^{(2)} \\ \Psi_{n,2}^{(0)} & \Psi_{n,2}^{(1)} & \Psi_{n,2}^{(2)} \end{pmatrix} =: \mathbf{C}^{-n}\mathbf{M}\mathbf{D}^n, \tag{8.9}$$

where $n\in\mathbb{N}_*$, $\mathbf{C}_n$ is a diagonal matrix of constants chosen to fulfill the normalization condition in RHP-$\mathbf{N}$(a), $\mathbf{C} := \mathsf{diag}(C_0,C_1,C_2)$, see (2.13), and $\mathbf{D} := \mathsf{diag}\left(\Phi^{(0)},\Phi^{(1)},\Phi^{(2)}\right)$.

Observe that $\mathsf{det}(\mathbf{N})$ is an entire function in $\mathbb{C}\setminus\{\pm1,\pm a,\pm b,\pm ic\}$ since the determinants of the jump matrices in RHP-$\mathbf{N}$(b) are all equal to 1. Moreover, the normalization at infinity implies that $\mathsf{det}(\mathbf{N})(\infty)=1$ and therefore $\mathsf{det}(\mathbf{N})$ is a rational function. It also follows from (3.5) that near any of the points in $\{\pm1,\pm a,\pm b,\pm ic\}$ the entries of one of the columns of $\mathbf{N}$ are bounded and the other entries behave like $\mathcal{O}(|z-e|^{-1/4})$. Hence,

$$\mathsf{det}(\mathbf{N})(z) = \mathcal{O}\left(|z-e|^{-1/2}\right) \quad \text{as} \quad z\to\{\pm1,\pm a,\pm b,\pm ic\},$$

and therefore $\mathsf{det}(\mathbf{N})\equiv 1$.

8.4 *Local Parametrices*

Denote by U_e, $e\in\{\pm1,\pm a,\pm b,\pm ic\}$, a disk centered at e of small enough radius so that $\Sigma_e := U_e\cap\Sigma_\mathbf{Z}$ consists of disjoint, except at e, analytic arcs. We are seeking a solution of the following RHP-$\mathbf{P}_e$:

(a) $\mathbf{P}_e$ is analytic in $U_e\setminus\Sigma_e$;

(b) $\mathbf{P}_e$ has continuous traces on each side of Σ_e° that satisfy RHP-$\mathbf{Z}$(b) within U_e;

(c) $\mathbf{P}_e$ is either bounded or has the behavior near e within U_e described by RHP-$\mathbf{Z}$(c);

(d) $\mathbf{P}_e = \mathbf{M}\left(\mathbf{I}+\mathcal{O}(1/n)\right)\mathbf{D}^n$ uniformly on $\partial U_e\setminus\Sigma_\mathbf{Z}$, where $\mathbf{M}$ and $\mathbf{D}$ are defined by (8.9).

We solve each RHP-$\mathbf{P}_e$ only for $n\in\mathbb{N}_*$. For these indices the above problem is well-posed as $\mathsf{det}(\mathbf{N})\equiv1$ and therefore $\mathbf{N}^{-1}$ is an analytic matrix function in $\mathbb{C}\setminus\Sigma_\mathbf{N}$. In fact, the solution does not depend on the actual choice of $\mathbb{N}_*$, however, the term $\mathcal{O}(1/n)$ in RHP-$\mathbf{P}_e$(d) may depend on the choice of this subsequence.

In solving RHP-$\mathbf{P}_e$, it will be convenient to use the notation $\sigma_3 = \begin{pmatrix}1&0\\0&-1\end{pmatrix}$ and introduce the following matrix transformations $T_1\mathbf{A}$, $T_2\mathbf{A}$, and $T_3\mathbf{A}$ given by

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & [\mathbf{A}]_{11} & [\mathbf{A}]_{12} \\ 0 & [\mathbf{A}]_{21} & [\mathbf{A}]_{22} \end{pmatrix}, \quad \begin{pmatrix} [\mathbf{A}]_{11} & 0 & [\mathbf{A}]_{12} \\ 0 & 1 & 0 \\ [\mathbf{A}]_{21} & 0 & [\mathbf{A}]_{22} \end{pmatrix}, \quad \text{and} \quad \begin{pmatrix} [\mathbf{A}]_{11} & [\mathbf{A}]_{12} & 0 \\ [\mathbf{A}]_{21} & [\mathbf{A}]_{22} & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

respectively, where $[\mathbf{A}]_{ik}$ is the (i,k)-th entry of $\mathbf{A}$. Observe that $T_j(\mathbf{AB}) = T_j(\mathbf{A})T_j(\mathbf{B})$ for all 2×2 matrices $\mathbf{A}, \mathbf{B}$.

8.4.1 RHP-$\mathbf{P}_{\pm 1}$

In [25], a 2×2 matrix function was constructed out of Bessel and Hankel functions that solves RHP-$\mathbf{\Psi}$:

(a) $\mathbf{\Psi}$ is holomorphic in $\mathbb{C}\setminus(I_+\cup I_-\cup(-\infty,0])$, where $I_\pm := \{\zeta : \arg(\zeta) = \pm 2\pi/3\}$, all the rays are oriented towards the origin;

(b) $\mathbf{\Psi}$ has continuous traces on $I_+\cup I_-\cup(-\infty,0)$ that satisfy

$$\mathbf{\Psi}_+ = \mathbf{\Psi}_- \begin{cases} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} & \text{on} \quad I_\pm, \\ \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & \text{on} \quad (-\infty,0); \end{cases}$$

(c) $\mathbf{\Psi}(\zeta) = \mathcal{O}(\log|\zeta|)$ as $\zeta\to 0$;

(d) $\mathbf{\Psi}$ has the following behavior near ∞:

$$\mathbf{\Psi}(\zeta) = \left(2\pi\zeta^{1/2}\right)^{-\sigma_3/2}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix}\left(\mathbf{I}+\mathcal{O}\left(\zeta^{-1/2}\right)\right)\exp\left\{2\zeta^{1/2}\sigma_3\right\}$$

uniformly in $\mathbb{C}\setminus(I_+\cup I_-\cup(-\infty,0])$.

Furthermore, $\sigma_3\mathbf{\Psi}\sigma_3$ solves the same R-H problem only with the reversed orientation of all the rays. Notice also that RHP-$\mathbf{\Psi}$(d) should be replaced in this case by

$$\sigma_3\mathbf{\Psi}(\zeta)\sigma_3 = \left(2\pi\zeta^{1/2}\right)^{-\sigma_3/2}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}\left(\mathbf{I}+\mathcal{O}\left(\zeta^{-1/2}\right)\right)\exp\left\{2\zeta^{1/2}\sigma_3\right\}.$$

To carry $\mathbf{\Psi}$ from the ζ-plane to U_e, $e\in\{\pm 1\}$, we need to introduce local conformal maps. To this end, set

$$g_e(z) := \frac{1}{2}\int_e^z (h_0 - h_2)(t)\,dt = \frac{1}{2}\log\left(\Phi^{(0)}(z)/\Phi^{(2)}(z)\right),$$

$z\in U_e\setminus[-1,1]$, where the second equality follows from (2.5) and (2.9). As mentioned after (6.4), g_e has purely imaginary traces on $(-1,1)\cap U_e$ that differ by a sign. Moreover, since g_e vanishes at e as a square root, g_e^2 is conformal in U_e. Furthermore,

$$\begin{cases} g_e^2(\{x:\ \mathrm{sgn}(e)x>1\}\cap U_e) & \subset & \{z : z>0\}, \\ g_e^2((-1,1)\cap U_e) & \subset & \{z : z<0\}, \\ g_e^2(\Delta_{2\pm}\cap U_e) & \subset & \{z:\ \mathrm{sgn}(e)\arg(z) = \pm 2\pi/3\}. \end{cases}$$

Indeed, the first property follows from (2.4) and (6.11) while the second is a consequence of the fact that g_e has purely imaginary traces there. The last property is the requirement we impose on the arcs $\Delta_{2\pm}$. Choosing the branch of $g_e^{1/2}$ which is positive on $\{x:\ \mathrm{sgn}(e)x>1\}\cap U_e$, one has on $(-1,1)\cap U_e$ that

$$g_{e+}^{1/2} = \mathrm{sgn}(e)ig_{e-}^{1/2}. \tag{8.10}$$

Now, it can readily be verified that the matrix function

$$\mathbf{P}_e := \mathsf{E}_e\mathsf{T}_2\mathbf{\Psi}_e\left(n^2g_e^2/4\right)\mathbf{W}_e, \tag{8.11}$$

satisfies RHP-$\mathbf{P}_e$(a,b,c) for any holomorphic matrix function E_e, where $\mathbf{\Psi}_1 := \mathbf{\Psi}$, $\mathbf{\Psi}_{-1} := \sigma_3\mathbf{\Psi}\sigma_3$, and

$$\mathbf{W}_e := \mathrm{diag}\left(\left(\Phi^{(0)}\Phi^{(2)}\right)^{n/2}/\sqrt{\rho_2^*}, \left(\Phi^{(1)}\right)^n, \left(\Phi^{(0)}\Phi^{(2)}\right)^{n/2}\sqrt{\rho_2^*}\right). \tag{8.12}$$

Moreover, one has on ∂U_e that

$$\mathbf{P}_e = \mathsf{E}_e\mathsf{T}_2\left(\rho_2^{*-\sigma_3/2}(\pi n g_e)^{-\sigma_3/2}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & \mathrm{sgn}(e)i \\ \mathrm{sgn}(e)i & 1 \end{pmatrix}\right)(\mathbf{I}+\mathcal{O}(1/n))\mathbf{D}^n. \tag{8.13}$$

Thus, it only remains to choose $\mathbf{E}_e$ so that RHP-$\mathbf{P}_e$(d) is fulfilled. Direct computation using RHP-$\mathbf{N}$(b) and (8.10) shows that the matrix

$$\mathbf{E}_e := \mathbf{M}\mathsf{T}_2\left(\rho_2^{*\sigma_3/2}(\pi n g_e)^{\sigma_3/2}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -\mathrm{sgn}(e)i \\ -\mathrm{sgn}(e)i & 1\end{pmatrix}\right) \tag{8.14}$$

is holomorphic in $U_e \setminus \{e\}$. As the entries of $\mathbf{M}$ behave like $|z-e|^{-1/4}$ as $z \to e$ by (3.5), the entries of $\mathbf{E}_e$ can have at most a square root singularity there. Thus, $\mathbf{E}_e$ is holomorphic throughout U_e as desired.

8.4.2 RHP-$\mathbf{P}_{\pm a}$

To solve RHP-$\mathbf{P}_{\pm a}$, we again use the matrix $\boldsymbol{\Psi}$. In this case we have an additional complication coming from the jumps on $(-b,-a)\cup(a,b)$. To circumvent it, we shall need the following fact about the matrix $\boldsymbol{\Psi}$:

$$[\boldsymbol{\Psi}]_{11}(\zeta) = I_0(2\zeta^{1/2}) \quad \text{and} \quad [\boldsymbol{\Psi}]_{21}(\zeta) = 2\pi i\zeta^{1/2}I_0'(2\zeta^{1/2}) \tag{8.15}$$

within $|\arg(z)| < 2\pi/3$, where I_0 is the modified Bessel function of order 0. Observe that both functions above are in fact entire in the whole complex plane.

Define

$$g_e(z) := \frac{1}{2}\int_e^z (h_0 - h_1)(t)dt = \frac{1}{2}\log\left(\Phi^{(0)}(z)/\Phi^{(1)}(z)\right), \tag{8.16}$$

$z \in U_e \setminus [-a,a]$. As mentioned after (6.7), g_e has purely imaginary traces on $(-a,a)\cap U_e$ that differ by a sign. Moreover, since g_e vanishes at e as a square root, g_e^2 is conformal in U_e. Furthermore,

$$\begin{cases} g_e^2(\{x: \mathrm{sgn}(e)x > a\}\cap U_e) & \subset & \{z: z>0\}, \\ g_e^2((-a,a)\cap U_e) & \subset & \{z: z<0\}, \\ g_e^2(\Delta_{1\pm}\cap U_e) & \subset & \{z: \mathrm{sgn}(e)\arg(z) = \pm 2\pi/3\}, \end{cases}$$

where the first property follows from (6.6) and (6.9), the second is a consequence of the fact that g_e has purely imaginary traces there, and the third is a requirement we impose on the arcs $\Delta_{1\pm}$. Choosing the branch of $g_e^{1/2}$ which is positive on $\{x: \mathrm{sgn}(e)x > a\}\cap U_e$, we see that (8.10) holds on $(-a,a)\cap U_e$.

We further define

$$\begin{cases} F_{n1}(z) & := & \rho_2(z)\left(\Phi^{(2)}(z)\right)^{-3n/2} I_0(ng_e(z))\frac{1}{2\pi i}\log\frac{z-b}{z-a}, \\ F_{n2}(z) & := & \rho_2(z)\left(\Phi^{(2)}(z)\right)^{-3n/2}\pi i n I_0'(ng_e(z))\frac{1}{2\pi i}\log\frac{z-b}{z-a}, \end{cases}$$

where I_0 is the modified Bessel function of order 0, see (8.15). The above functions are holomorphic in $U_a \setminus [a,b]$ and

$$F_{ni+} - F_{ni-} = [\boldsymbol{\Psi}]_{i1}(n^2g_a^2/4)\rho_2\left(\Phi^{(2)}\right)^{-3n/2}$$

on (a,b). According to [16, Eq. 10.40.5],

$$\begin{aligned} (ng_a)^{1/2}F_{n1} &= \left(e^{ng_a}\mathcal{O}(1) + e^{-ng_a}\mathcal{O}(1)\right)\left(\Phi^{(2)}\right)^{-3n/2} \\ &= \left(\frac{\Phi^{(0)}}{\Phi^{(2)}}\right)^n\mathcal{O}(1) + \left(\frac{\Phi^{(1)}}{\Phi^{(2)}}\right)^n\mathcal{O}(1) = o(1) \end{aligned}$$

uniformly on ∂U_a by (8.16) and since $\partial U_a \subset \Omega_{201}$ by Theorem 3 and the choice of the radius of U_a. Clearly, $o(1)$ in the above equality is geometric. Moreover, a completely analogous estimate holds for F_{n2}. Given these two functions, we can set

$$\boldsymbol{\Psi}_a := \begin{pmatrix} [\boldsymbol{\Psi}]_{11}(n^2g_a^2/4) & [\boldsymbol{\Psi}]_{12}(n^2g_a^2/4) & F_{n1} \\ [\boldsymbol{\Psi}]_{21}(n^2g_a^2/4) & [\boldsymbol{\Psi}]_{22}(n^2g_a^2/4) & F_{n2} \\ 0 & 0 & 1 \end{pmatrix}.$$

Then the solution of RHP-$\mathbf{P}_a$ is given by $\mathbf{P}_a := \mathsf{E}_a \boldsymbol{\Psi}_a \boldsymbol{W}_a$, where

$$\begin{cases} \boldsymbol{W}_a & := & \operatorname{diag}\left(\left(\Phi^{(0)}\Phi^{(1)}\right)^{n/2}/\sqrt{\rho_1}, \left(\Phi^{(0)}\Phi^{(1)}\right)^{n/2}\sqrt{\rho_1}, \left(\Phi^{(2)}\right)^{n}\right) \\ \mathsf{E}_a & := & \mathsf{M}\mathsf{T}_3\left(\rho_1^{\sigma_3/2}(\pi n g_a)^{\sigma_3/2}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}\right). \end{cases}$$

To verify RHP-$\mathbf{P}_a$(d), observe that

$$\mathsf{T}_3\left(\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}(\pi n g_a)^{\sigma_3/2}\right)\boldsymbol{\Psi}_a \mathsf{T}_3\left(\Phi^{(0)}/\Phi^{(1)}\right)^{-n\sigma_3/2} = \mathbf{I} + \mathcal{O}(1/n)$$

by the asymptotic properties of F_{ni}. The matrix $\mathbf{P}_{-a}$ solving RHP-$\mathbf{P}_{-a}$ can be constructed analogously.

8.4.3 RHP-$\mathbf{P}_{\pm b}$

In [13], a 2×2 matrix was constructed out of Airy functions that solves RHP-$\boldsymbol{\Phi}$:

(a) $\boldsymbol{\Phi}$ is holomorphic in $\mathbb{C} \setminus (I_+ \cup I_- \cup (-\infty, \infty))$, where the real line is oriented from left to right;

(b) $\boldsymbol{\Phi}$ has continuous traces on $I_+ \cup I_- \cup (-\infty, 0) \cup (0, \infty)$ that satisfy

$$\boldsymbol{\Phi}_+ = \boldsymbol{\Phi}_- \begin{cases} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} & \text{on} \quad I_\pm, \\ \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & \text{on} \quad (-\infty, 0), \\ \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} & \text{on} \quad (0, \infty); \end{cases}$$

(c) $\boldsymbol{\Phi}$ is bounded around the origin;

(d) $\boldsymbol{\Phi}$ has the following behavior near ∞:

$$\boldsymbol{\Phi}(\zeta) = \zeta^{-\sigma_3/4}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix}\left(\mathbf{I} + \mathcal{O}\left(\zeta^{-3/2}\right)\right)\exp\left\{-\frac{2}{3}\zeta^{3/2}\sigma_3\right\}$$

uniformly in $\mathbb{C} \setminus (I_+ \cup I_- \cup (-\infty, \infty))$.

Again, $\sigma_3\boldsymbol{\Phi}\sigma_3$ solves the same R-H problem only with the reversed orientation of all the rays. As in the case of $\boldsymbol{\Psi}$,

$$\sigma_3\boldsymbol{\Phi}(\zeta)\sigma_3 = \zeta^{-\sigma_3/4}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}\left(\mathbf{I} + \mathcal{O}\left(\zeta^{-3/2}\right)\right)\exp\left\{-\frac{2}{3}\zeta^{3/2}\sigma_3\right\}.$$

To map $\boldsymbol{\Phi}$ into U_e, $e \in \{\pm b\}$, define

$$g_e(z) := -\frac{1}{2}\int_e^z (h_0 - h_2)(t)dt = -\frac{1}{2}\log\left(\Phi^{(0)}(z)/\Phi^{(2)}(z)\right),$$

$z \in U_e \setminus ([-1, -b] \cup [b, 1])$. As before, g_e has purely imaginary traces on $((-1, -b) \cup (b, 1)) \cap U_e$ that differ by a sign. Moreover, since g_e vanishes at e as $(z - e)^{3/2}$, $g_e^{2/3}$ is conformal in U_e. Furthermore,

$$\begin{cases} g_e^{2/3}(\{x : \operatorname{sgn}(e)x < b\} \cap U_e) & \subset & \{z : z > 0\}, \\ g_e^{2/3}(((-1 - b) \cup (b, 1)) \cap U_e) & \subset & \{z : z < 0\}, \\ g_e^{2/3}(\Delta_{2\pm} \cap U_e) & \subset & \{z : -\operatorname{sgn}(e)\arg(z) = \pm 2\pi/3\}, \end{cases}$$

where the first property follows from (6.6) and (6.9), the second is a consequence of the fact that g_e has purely imaginary traces there, and the third is a requirement we impose on the arcs $\Delta_{2\pm}$. Choosing the branch of $g_e^{1/6}$ which is positive on $\{x : \operatorname{sgn}(e)x < b\} \cap U_e$, one has on $((-1, -b) \cup (b, 1)) \cap U_e$ that

$$g_{e+}^{1/6} = -\operatorname{sgn}(e) i g_{e-}^{1/6}. \tag{8.17}$$

As in the previous cases, one can verify that the solution of RHP-$\mathbf{P}_e$ is given by

$$\mathrm{P}_e := \mathrm{E}_e \mathrm{T}_2 \boldsymbol{\Phi}_e\left((3n/2)^{2/3} g_e^{2/3}\right) \boldsymbol{W}_e, \tag{8.18}$$

where $\boldsymbol{\Phi}_{-b} := \boldsymbol{\Phi}$ and $\boldsymbol{\Phi}_b := \sigma_3 \boldsymbol{\Phi} \sigma_3$, $\boldsymbol{W}_e$ is defined by (8.12), and

$$\mathrm{E}_e := \mathrm{M}\mathrm{T}_2\left(\rho_2^{*\sigma_3/2}\,(3n g_e/2)^{\sigma_3/6}\,\frac{1}{\sqrt{2}}\begin{pmatrix}1 & -\mathrm{sgn}(e)\mathrm{i}\\ -\mathrm{sgn}(e)\mathrm{i} & 1\end{pmatrix}\right), \tag{8.19}$$

whose holomorphy can be checked as in the previous cases using (8.17).

8.4.4 RHP-$\mathbf{P}_{\pm\mathrm{i}c}$

To map $\boldsymbol{\Phi}$ into U_e, $e \in \{\pm \mathrm{i}c\}$, set $\mathrm{sgn}(\pm\mathrm{i}c) = \pm$ and define

$$g_e(z) := -\frac{1}{2}\int_e^z (h_1 - h_2)(t)dt = -\frac{1}{2}\log\left(\Phi^{(1)}(z)/\Phi^{(2)}(z)\right),$$

$z \in U_e \setminus \Gamma$. Since Γ is the branch cut for h_1 and h_2, the traces of g_e on $\Gamma \cap U_e$ differ by a sign. Moreover, since g_e vanishes at e as $(z-e)^{3/2}$, $g_e^{2/3}$ is conformal in U_e. The following are conditions we impose on the arcs Γ, Γ_2, and $\Gamma_{1\pm}$:

$$\begin{cases} g_e^{2/3}(\Gamma_2 \cap U_e) & \subset & \{z : z > 0\},\\ g_e^{2/3}(\Gamma \cap U_e) & \subset & \{z : z < 0\},\\ g_e^{2/3}(\Gamma_{1\pm} \cap U_e) & \subset & \{z :\ \mathrm{sgn}(e)\arg(z) = \pm 2\pi/3\}. \end{cases}$$

Choosing the branch of $g_e^{1/6}$ which is positive on $\Gamma_2 \cap U_e$, we see that (8.17) holds on $\Gamma \cap U_e$ with $-\mathrm{sgn}(e)$ replaced by $\mathrm{sgn}(e)$. Then the solution of RHP-$\mathbf{P}_e$ is given by

$$\mathrm{P}_e := \mathrm{E}_e \mathrm{T}_1 \boldsymbol{\Phi}_e\left((3n/2)^{2/3} g_e^{2/3}\right) \boldsymbol{W}_e, \tag{8.20}$$

where $\boldsymbol{\Phi}_{\mathrm{i}c} := \boldsymbol{\Phi}$ and $\boldsymbol{\Phi}_{-\mathrm{i}c} := \sigma_3 \boldsymbol{\Phi} \sigma_3$, and

$$\begin{cases} \boldsymbol{W}_e & := & \mathrm{diag}\left(\left(\Phi^{(0)}\right)^n, \left(\Phi^{(1)}\Phi^{(2)}\right)^{n/2}\sqrt{\rho_1/\rho_2}, \left(\Phi^{(1)}\Phi^{(2)}\right)^{n/2}\sqrt{\rho_2/\rho_1}\right),\\ \mathrm{E}_e & := & \mathrm{M}\mathrm{T}_1\left((\rho_2/\rho_1)^{\sigma_3/2}\,(3n g_e/2)^{\sigma_3/6}\,\frac{1}{\sqrt{2}}\begin{pmatrix}1 & -\mathrm{sgn}(e)\mathrm{i}\\ -\mathrm{sgn}(e)\mathrm{i} & 1\end{pmatrix}\right). \end{cases} \tag{8.21}$$

8.5 *Final R-H Problem*

Consider the following Riemann-Hilbert problem (RHP-$\mathbf{R}$):

(a) $\mathbf{R}$ is analytic in $\overline{\mathbb{C}} \setminus \Sigma_{\mathbf{R}}$, where $\Sigma_{\mathbf{R}}$ is the contour shown in Figure 14, and $\mathbf{R}(\infty) = \mathbf{I}$;
(b) $\mathbf{R}$ has continuous traces on each side of $\Sigma_{\mathbf{R}}^{\circ}$ that satisfy

$$\mathbf{R}_+ = \mathbf{R}_-\begin{cases} (\mathbf{M}\mathbf{D}^n)\mathbf{J}_{\mathbf{Z}}(\mathbf{M}\mathbf{D}^n)^{-1} & \text{on} \quad \Sigma_{\mathbf{R}}^{\circ} \cap \Sigma_{\mathbf{Z}},\\ \mathrm{P}_e(\mathbf{M}\mathbf{D}^n)^{-1} & \text{on} \quad \partial U_e, \quad e \in \{\pm 1, \pm a, \pm b, \pm \mathrm{i}c\}, \end{cases}$$

where $\mathbf{J}_{\mathbf{Z}}$ was defined in (8.8), while $\mathbf{M}$ and $\mathbf{D}$ were introduced after (8.9).

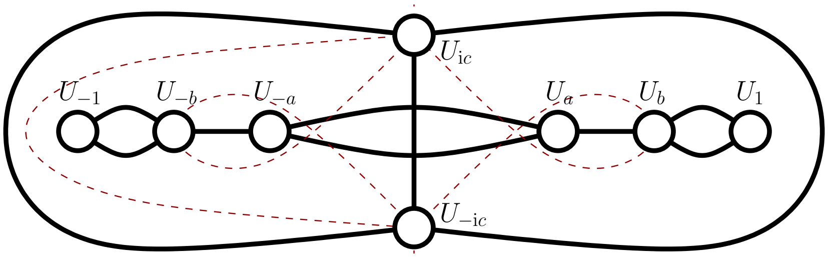

Figure 14. The contour $\Sigma_{\mathbf{R}}$: solid lines. The dashed lines represent the relevant borders of the domains Ω_{ijk}, see Figure 3(a).

Let us prove that the jumps of $\mathbf{R}$ are uniformly close to $\mathbf{I}$ for $n \in \mathbb{N}_*$. In Section 8.3 we have shown that $\det(\mathbf{N}) =$, while $\det(\mathbf{D}) = 1$ by (2.10) and $\det(\mathbf{C}) = 1$ by (2.13). Hence, $\det(\mathbf{M}) = 1$ and therefore $\mathbf{M}^{-1} = \mathrm{adj}(\mathbf{M})$, where $\mathrm{adj}(\mathbf{M})$ is the adjoint matrix of $\mathbf{M}$. Thus,

$$\mathbf{M}\big(\mathbf{I} + \mathcal{O}(\cdot)\big)\mathbf{M}^{-1} = \mathbf{I} + \mathbf{M}\mathcal{O}(\cdot)\mathrm{adj}(\mathbf{M}) = \mathbf{I} + \mathcal{O}(\cdot) \tag{8.22}$$

uniformly away from $\{\pm 1, \pm a, \pm b, \pm ic\}$ by (7.30). Therefore, it follows from RHP-$\mathbf{P}_e$(d) that

$$\mathbf{P}_e\big(\mathbf{M}\mathbf{D}^n\big)^{-1} = \mathbf{I} + \mathbf{M}\mathcal{O}(1/n)\mathbf{M}^{-1} = \mathbf{I} + \mathcal{O}(1/n) \tag{8.23}$$

uniformly on each ∂U_e. Furthermore, we can write

$$\mathbf{J}_\mathbf{Z} = \mathbf{I} + \rho_{j,k}\mathbf{E}_{j,k}, \quad j \neq k, \quad j,k \in \{0,1,2\},$$

where $\mathbf{E}_{j,k}$ is the matrix with all zero entries except for the $(j+1,k+1)$-st one, which is 1, and $\rho_{j,k}$ is always a combination of ρ_1 and ρ_2 (particular values of j,k and the value of the entry depend on the arc in question). Thus,

$$\mathbf{D}^n\mathbf{J}_\mathbf{Z}\mathbf{D}^{-n} = \mathbf{I} + \left(\frac{\Phi^{(j)}}{\Phi^{(k)}}\right)^n \rho_{j,k}\mathbf{E}_{j,k} = \mathbf{I} + \mathcal{O}\big(C_\mathbf{R}^{-n}\big)$$

uniformly on $\Sigma_\mathbf{Z} \cap \Sigma_\mathbf{R}$ for some constant $C_\mathbf{R} > 1$ by Theorem 3 (it is a simple examination of the five relevant cases). Therefore, we get from (8.22) that

$$\big(\mathbf{M}\mathbf{D}^n\big)\mathbf{J}_\mathbf{Z}\big(\mathbf{M}\mathbf{D}^n\big)^{-1} = \mathbf{I} + \mathcal{O}\big(C_\mathbf{R}^{-n}\big) \tag{8.24}$$

uniformly on $\Sigma_\mathbf{Z} \cap \Sigma_\mathbf{R}$. The relations (8.23) and (8.24) together with [12, Corollary 7.108] imply that RHP-$\mathbf{R}$ is solvable for all $n \in \mathbb{N}_*$ large enough and satisfies

$$\mathbf{R} = \mathbf{I} + \mathcal{O}(1/n), \quad \mathbf{R}(\infty) = \mathbf{I}, \tag{8.25}$$

uniformly in $\overline{\mathbb{C}}$, that is, including the boundary values on $\Sigma_\mathbf{R}$.

8.6 *Asymptotics of Hermite-Padé Approximants*

Inverting (8.5) and (8.3), we get from (5.4) that

$$Q_n(z) = [\mathbf{Z}]_{11}(z) + \frac{1}{\rho_i^*(z)}\left\{\begin{array}{rl} \pm[\mathbf{Z}]_{1i+1}(z), & z \in O_{i\pm}, \\ 0, & \text{otherwise}, \end{array}\right. \tag{8.26}$$

where $\rho_1^* = \rho_1$;

$$R_{\vec{n}}^{(1)}(z) = [\mathbf{Z}]_{12}(z) - \frac{\rho_1(z)}{\rho_2(z)}\left\{\begin{array}{rl} -[\mathbf{Z}]_{13}(z), & z \in O_0, \\ [\mathbf{Z}]_{13}(z), & z \in O_1, \\ 0, & \text{otherwise}, \end{array}\right. \tag{8.27}$$

for $z \notin F_1$; and

$$R_{\vec{n}}^{(2)}(z) = \left\{\begin{array}{rl} 0, & z \in O_1 \\ [\mathbf{Z}]_{13}(z), & \text{otherwise} \end{array}\right\} + \frac{\rho_2(z)}{\rho_1(z)}\left\{\begin{array}{rl} [\mathbf{Z}]_{12}(z), & O_1 \cup O_2 \\ 0, & \text{otherwise} \end{array}\right\} \tag{8.28}$$

for $z \notin F_2$.

Let $\mathbf{R}$ be the solution of RHP-$\mathbf{R}$. Then

$$\mathbf{Z} = \mathbf{C}^{-n}\mathbf{R}\left\{\begin{array}{lll} \mathbf{M}\mathbf{D}^n & \text{in} & \mathbb{C} \setminus \bigcup_e U_e, \\ \mathbf{P}_e & \text{in} & U_e, \quad e \in \{\pm 1, \pm a, \pm b, \pm ic\}, \end{array}\right. \tag{8.29}$$

solves RHP-$\mathbf{Z}$ for all $n \in \mathbb{N}_*$ large enough. Denote the first row of $\mathbf{R}$ by $(1 + \upsilon_{n,0} \quad \upsilon_{n,1} \quad \upsilon_{n,2})$. It follows from (8.25) that

$$|\upsilon_{n,k}(\infty)| = 0 \quad \text{and} \quad |\upsilon_{n,k}(z)| = \mathcal{O}(1/n) \quad \text{uniformly for} \quad z \in \mathbb{C}, \tag{8.30}$$

meaning that $\upsilon_{n,k}(z)$ is replaced by $\upsilon^{\pm}_{n,k}(z)$ when $z \in \Sigma_{\mathbf{R}}$. If $z \notin U_e$, $e \in \{\pm 1, \pm a, \pm b, \pm ic\}$, then

$$(8.31) \qquad [\boldsymbol{Z}]_{1k+1}(z) = C_n \Psi^{(k)}_{n,0}(z) + C_n \sum_{j=0}^{2} \upsilon_{n,j}(z) \Psi^{(k)}_{n,j}(z), \quad k \in \{0,1,2\},$$

according to (4.2), where the functions are replaced by their traces when necessary.

Formula (8.31) is valid for $z \in U_{ic} \cup U_{-ic}$ when $k = 0$ and for $z \in U_e$, $e \in \{\pm b, \pm 1\}$, when $k = 1$. Indeed, in these cases $\boldsymbol{P}_e = \boldsymbol{M}\mathsf{T}_{k+1}(\cdot)\boldsymbol{W}_e$, see (8.20) and (8.21), (8.11) and (8.14), (8.18) and (8.19). As the $(k+1)$-st column of $\boldsymbol{W}_e$ is the same as the $(k+1)$-st column of $\boldsymbol{D}^n$, the $(k+1)$-st column of $\boldsymbol{P}_e$ is the same as the $(k+1)$-st column of $\boldsymbol{M}\boldsymbol{D}^n$ from which the claim follows.

To estimate the sum on the right-hand side of (8.31), recall that

$$(8.32) \qquad \Psi_{n,j} = \Psi_{n,0} \Theta_j \Theta_{n,j} \Theta^{-1}_{n,0},$$

see (7.27), where $\Theta_j \Theta_{n,j} \Theta^{-1}_{n,0}$ is a rational function on $\mathfrak{R}$ with the divisor $\mathcal{D}_{n,j} + \infty^{(0)} - \mathcal{D}_{n,0} - \infty^{(j)}$. Then (8.30), the maximum modulus principle, and the same normal family argument as in (7.31) and (7.32) imply that

$$(8.33) \qquad \left| \upsilon_{n,j}(z) \Theta_j\big(z^{(k)}\big) \Theta_{n,j}\big(z^{(k)}\big) \Theta^{-1}_{n,0}\big(z^{(k)}\big) \right| = \mathcal{O}\big(1/n; \mathcal{D}_{n,0} \cap \mathfrak{R}^{(k)}\big)$$

uniformly in $\overline{\mathbb{C}}$, where the function on the left-hand side of (8.33) needs to be replaced by its traces when $z \in \Sigma_{\mathbf{R}} \cup \pi\big(\partial \mathfrak{R}^{(k)}\big)$. By combining (8.32) with (8.33) we get that

$$(8.34) \qquad \upsilon_{n,j}(z) \Psi^{(k)}_{n,j}(z) = \Psi^{(k)}_{n,0}(z) \mathcal{O}\big(1/n; \mathcal{D}_{n,0} \cap \mathfrak{R}^{(k)}\big), \quad j,k \in \{0,1,2\},$$

where $\mathcal{O}(\cdot)$ is uniform in $\overline{\mathbb{C}}$.

The first relation in (4.4) follows immediately from the first line of (8.26), (8.31), and (8.34). Moreover, (8.31) implies that the second line of (8.26) can be rewritten as

$$Q_{\vec{n}}(z) = C_n \left(\Psi^{(0)}_{n,0+}(z) + \Psi^{(0)}_{n,0-}(z) \right) + C_n \sum_{j=0}^{2} \upsilon_{n,j}(z) \left(\Psi^{(0)}_{n,j+}(z) + \Psi^{(0)}_{n,j-}(z) \right)$$

for $z \in O_{1+} \cup O_{1-} \cup O_{2+} \cup O_{2-}$ and $z \notin \overline{U}_e$, $e \in \{\pm b, \pm a, \pm 1\}$, where

$$\Psi^{(0)}_{n,j\pm}(z) = \begin{cases} \Psi^{(0)}_{n,j}(z), & z \in O_{i\pm}, \\ \mp \Psi^{(i)}_{n,j}(z)/\rho^{*}_{i}(z), & z \in O_{i\mp}, \end{cases} \qquad i \in \{1,2\}.$$

Clearly, each $\Psi^{(0)}_{n,j\pm}$ extends to a holomorphic function in $O_{i+} \cup O_{i-} \cup \Delta^{\circ}_{i}$ by (3.6) (recall that $\Psi_{n,1}$ and $\Psi_{n,2}$ also satisfy these relations). The first part of (4.5) now follows from (8.34).

Furthermore, (8.27), (8.31), and (8.34) imply the second line of (4.4) outside of $O_0 \cup O_1$ for $i = 1$. In the spirit of (4.3), define

$$\widehat{\Psi}^{(1)}_{n,j+}(z) = \begin{cases} \Psi^{(1)}_{n,j}(z), & z \in O_0, \\ \Psi^{(2)}_{n,j}(z)(-\rho_1/\rho_2)(z), & z \in O_1, \end{cases}$$

which is holomorphic in $(O_0 \cup O_1 \cup \Delta^{\circ}_0) \setminus \Delta_{21}$ by (3.6), and

$$\widehat{\Psi}^{(1)}_{n,j-}(z) = \begin{cases} \Psi^{(1)}_{n,j}(z), & z \in O_1, \\ \Psi^{(2)}_{n,j}(z)(\rho_1/\rho_2)(z), & z \in O_0, \end{cases}$$

which is holomorphic in $(O_0 \cup O_1 \cup \Delta^{\circ}_0) \setminus \Delta_1$, again, by (3.6). Then (8.27) and (8.31) imply that

$$R^{(1)}_{\vec{n}}(z) = C_n \left(\widehat{\Psi}^{(1)}_{n,0+}(z) + \widehat{\Psi}^{(1)}_{n,0-}(z) \right) + C_n \sum_{j=0}^{2} \upsilon_{n,j}(z) \left(\widehat{\Psi}^{(1)}_{n,j+}(z) + \widehat{\Psi}^{(1)}_{n,j-}(z) \right).$$

for $z \in (O_0 \cup O_1 \cup \Delta_0^\circ) \setminus F_1$ and $z \notin U_e$, $e \in \{-1, -b, -a, \pm ic\}$. Clearly, formula (4.5) is an immediate consequence of (8.34). To finish the proof of (4.4) for $i = 1$, let us show that

$$\widehat{\Psi}^{(1)}_{n,j+} = \widehat{\Psi}^{(1)}_{n,0-}\mathcal{O}\big(1/n; \mathcal{D}_{n,0} \cap \mathfrak{R}^{(1)}\big)$$

locally uniformly in $\big(\mathrm{int}(\Gamma_1 \cup \Delta_{01-}) \cup \Delta_{01-}\big) \setminus \big(F_1 \cup \overline{U}_{-ic} \cup \overline{U}_{ic}\big)$. Indeed, we have that

$$\frac{\widehat{\Psi}^{(1)}_{n,j+}}{\widehat{\Psi}^{(1)}_{n,0-}} = -\frac{\rho_1 w_2}{\rho_2 w_1}\left(\frac{\Phi^{(2)}}{\Phi^{(1)}}\right)^n \frac{S^{(2)}_\rho S^{(2)}_{\vec{y}_n}\Theta^{(2)}_{n,j}\Theta^{(2)}_j}{S^{(1)}_\rho S^{(1)}_{\vec{y}_n}\Theta^{(1)}_{n,0}}$$

see (7.27). The claim now follows from Theorem 3 and the normal family argument along the lines of (7.31) and (7.32). This proves (4.4) outside of $\mathrm{int}(\Gamma_1 \cup \Delta_{01+})$. Analogously we can argue that

$$\widehat{\Psi}^{(1)}_{n,j-} = \widehat{\Psi}^{(1)}_{n,0+}\mathcal{O}\big(1/n; \mathcal{D}_{n,0} \cap \mathfrak{R}^{(2)}\big)$$

locally uniformly in $\big(\mathrm{int}(\Gamma_1 \cup \Delta_{01+}) \cup \Delta_{01+}\big) \setminus \big(F_1 \cup \overline{U}_{-ic} \cup \overline{U}_{ic}\big)$, which finishes the proof of (4.4) for $R^{(1)}_{\vec{n}}$. The proof of (4.4) and (4.5) for $R^{(2)}_{\vec{n}}$ can be completed analogously starting with (8.28).

9 RIEMANN-HILBERT ANALYSIS: CASE II

9.1 *Global Lenses*

Let $\mathbf{G}_1(u)$ and $\mathbf{G}_2(v)$ be defined by (8.1). Further, let $O_1 := \{z : \mathrm{Re}(z) < 0\}$ be the left half-plane. We orient the boundary of O_1, say Δ_{01} (the imaginary axis), so that O_1 lies to the left of Δ_{01} when the latter is traversed in the positive direction. Denote by Δ_{02} a simple Jordan curve lying within the right component of Ω_{021} containing all the singularities of ρ_2/ρ_1, see Figure 15 (this is always possible because of Condition 8). We orient Δ_{02} counter-clockwise and set O_2 to be the intersection of the exterior domain of Δ_{02} and the right half-plane $\{\mathrm{Re}(z) > 0\}$. Put

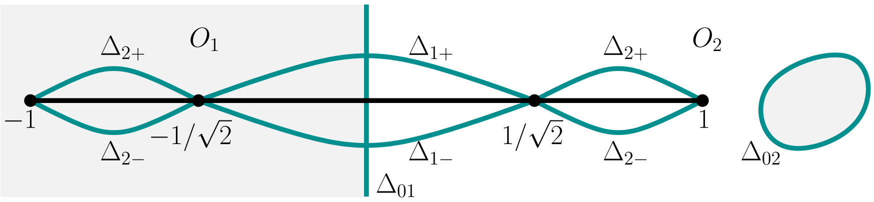

FIGURE 15. The lens Σ_Z without the circle $\{|z| = R\}$, the domains O_1 (shaded regions on the left) and O_2 (unshaded region), local lenses $\Delta_{1\pm}$ and $\Delta_{2\pm}$.

$$\mathbf{S} := \mathbf{G}_1(-\rho/2)\mathbf{G}_2(1/\rho)\mathbf{Y}\begin{cases} \mathbf{G}_2(-\rho_2/\rho_1)\mathbf{G}_1(\rho_1/\rho_2) & \text{in} \quad O_1, \\ \mathbf{G}_2(-\rho_2/\rho_1) & \text{in} \quad O_2, \\ \mathbf{I} & \text{in} \quad \mathbb{C} \setminus \big(\overline{O_1 \cup O_2}\big), \end{cases} \tag{9.1}$$

where $\rho := \rho_1(\infty)/\rho_2(\infty)$. Put $\Sigma_{\mathbf{S}} := [-1, 1] \cup \Delta_{01} \cup \Delta_{02}$. Then $\mathbf{S}$ solves RHP-$\mathbf{S}$:

(a) $\mathbf{S}$ is analytic in $\mathbb{C} \setminus \Sigma_{\mathbf{S}}$ and $\lim_{z\to\infty, \pm\mathrm{Re}(z)>0} \mathbf{S}(z)\mathrm{diag}\big(z^{-2n}, z^n, z^n\big) = \mathbf{G}_1(\mp\rho/2)$;

(b) $\mathbf{S}$ has continuous traces on $\Sigma^\circ_{\mathbf{S}} := \Sigma_{\mathbf{S}} \setminus \big\{\pm 1, \pm 1/\sqrt{2}, 0\big\}$ that satisfy

$$\mathbf{S}_+ = \mathbf{S}_- \begin{cases} \mathbf{J}(\rho_1, 0) & \text{on} \quad \Delta_1 \setminus \{0\}, \\ \mathbf{J}(0, \rho_2^*) & \text{on} \quad \Delta_2, \\ \mathbf{G}_1(\rho_1/\rho_2) & \text{on} \quad \Delta_{01}, \\ \mathbf{G}_2(\rho_2/\rho_1) & \text{on} \quad \Delta_{02}, \end{cases}$$

where ρ_2^* is defined by (8.4) and Δ_i in (2.8);

(c) $\mathbf{S}$ satisfies RHP-$\mathbf{Y}$(c) (see Section 5) with $[-1, 1]$ replaced by $\Sigma_{\mathbf{S}}$.

If RHP-S is solvable, then so is RHP-Y, and the solutions are connected via (9.1).

9.2 *Local Lenses*

As in Case I, we introduce additional arcs $\Delta_{1\pm}$ and systems of two arcs $\Delta_{2\pm}$ as in Figure 15, all oriented from left to right. We further denote by $O_{i\pm}$ the open sets bounded by Δ_i and the arcs $\Delta_{i\pm}$, $i \in \{1,2\}$. Set

$$\mathbf{Z} := \mathbf{S}\mathbf{L}_i^{\mp 1} \quad \text{in} \quad O_{i\pm}, \tag{9.2}$$

where the matrices $\mathbf{L}_i$ are defined by (8.6). Put $\Sigma_{\mathbf{Z}} := \Sigma_{\mathbf{S}} \cup \Delta_{1+} \cup \Delta_{1-} \cup \Delta_{2+} \cup \Delta_{2-}$. Then it can readily be checked that $\mathbf{Z}$ solves RHP-$\mathbf{Z}$:

(a) $\mathbf{Z}$ is analytic in $\mathbb{C} \setminus \Sigma_{\mathbf{Z}}$ and $\lim_{z\to\infty, \pm\mathrm{Re}(z)>0} \mathbf{Z}(z)\mathrm{diag}\left(z^{-2n}, z^n, z^n\right) = \mathbf{G}_1(\mp\rho/2)$;

(b) $\mathbf{Z}$ has continuous traces on each side of $\Sigma_{\mathbf{Z}}^\circ := \Sigma_{\mathbf{Z}} \setminus \left\{\pm 1, \pm 1/\sqrt{2}, 0\right\}$ that satisfy

$$\mathbf{Z}_+ = \mathbf{Z}_- \begin{cases} \mathbf{J}_i & \text{on} \quad \Delta_i^\circ \setminus \{0\}, \quad i \in \{1,2\}, \\ \mathbf{J}_{\mathbf{Z}} & \text{on} \quad \bigcup_{i=1}^2 (\Delta_{0i} \cup \Delta_{i+} \cup \Delta_{i-}), \end{cases}$$

where $\mathbf{J}_i$ are defined by (8.7) and

$$\mathbf{J}_{\mathbf{Z}} := \begin{cases} \mathbf{G}_1(\rho_1/\rho_2) & \text{on} \quad \Delta_{01}, \\ \mathbf{G}_2(\rho_2/\rho_1) & \text{on} \quad \Delta_{02}, \\ \mathbf{L}_i & \text{on} \quad \Delta_{i\pm}, \quad i \in \{1,2\}; \end{cases} \tag{9.3}$$

(c) $\mathbf{Z}$ satisfies RHP-S(c) with $\Sigma_{\mathbf{S}}$ replaced by $\Sigma_{\mathbf{Z}}$.

As before, if RHP-Z is solvable, then so is RHP-S, and the solutions are connected via (9.2).

9.3 *Global Parametrix*

Let $\mathbf{N} = \mathbf{C}^{-n}\mathbf{M}\mathbf{D}^n$ be given by (8.9). Then it is a solution of the following Riemann-Hilbert problem (RHP-$\mathbf{N}$):

(a) $\mathbf{N}$ is analytic in $\mathbb{C} \setminus [-1,1]$ and $\lim_{z\to\infty} \mathbf{N}(z)\mathrm{diag}\left(z^{-2n}, z^n, z^n\right) = \mathbf{I}$;

(b) $\mathbf{N}$ has continuous traces on each side of Δ_i°, $i \in \{1,2\}$, that satisfy $\mathbf{N}_+ = \mathbf{N}_-\mathbf{J}_i$.

We cannot argue that $\det(\mathbf{M}) \equiv 1$ as in Section 8.3 since every entry of $\mathbf{M}$ behaves like $(z \mp 1/\sqrt{2})^{-1/3}$ as $z \to \pm 1/\sqrt{2}$. However, we can construct $\mathbf{M}^{-1}$ explicitly. Denote by $\widetilde{\mathbf{N}} = \mathbf{C}^{-n}\widetilde{\mathbf{M}}\mathbf{D}^n$ the matrix that satisfies RHP-N as above with ρ_1 and ρ_2^* replaced by $1/\rho_1$ and $1/\rho_2^*$. It follows from (7.29) that the construction (8.9) of the matrices $\mathbf{N}$ and $\widetilde{\mathbf{N}}$ is simultaneously applicable or not applicable for each index n. Observe that

$$\left(\mathbf{M}\widetilde{\mathbf{M}}^{\mathsf{T}}\right)_-^{-1}\left(\mathbf{M}\widetilde{\mathbf{M}}^{\mathsf{T}}\right)_+ = \left(\widetilde{\mathbf{M}}_+^{\mathsf{T}}\right)^{-1}(\mathbf{D}_-/\mathbf{D}_+)^{2n}\,\widetilde{\mathbf{M}}_+^{\mathsf{T}} = \left(\widetilde{\mathbf{M}}_+^{\mathsf{T}}\right)^{-1}\widetilde{\mathbf{M}}_+^{\mathsf{T}} = \mathbf{I}$$

on $\pi(\boldsymbol{\alpha}_1)$ and $\pi(\boldsymbol{\beta}_1)$ by (2.11) and (2.15). Moreover,

$$\left(\mathbf{M}\widetilde{\mathbf{M}}^{\mathsf{T}}\right)_-^{-1}\left(\mathbf{M}\widetilde{\mathbf{M}}^{\mathsf{T}}\right)_+ = \left(\widetilde{\mathbf{M}}_-^{\mathsf{T}}\right)^{-1}\mathbf{J}_i\widetilde{\mathbf{M}}_+^{\mathsf{T}} = \left(\widetilde{\mathbf{M}}_+\mathbf{J}_i^{\mathsf{T}}\widetilde{\mathbf{M}}_-^{-1}\right)^{\mathsf{T}} = \mathbf{I}$$

on Δ_i° since $\mathbf{J}_i^{\mathsf{T}} = \widetilde{\mathbf{J}}_i^{-1}$. It also follows from (3.5) that the entries of $\mathbf{M}$ and $\widetilde{\mathbf{M}}$ have at most $1/4$ and $1/3$-root singularities at ± 1 and $\pm 1/\sqrt{2}$, respectively (the functions $\Psi_{n,1}$ and $\Psi_{n,2}$ possess exactly the same behavior around those points as $\Psi_n = \Psi_{n,0}$). Hence, the product $\mathbf{M}\widetilde{\mathbf{M}}^{\mathsf{T}}$ is holomorphic in the entire complex plane. Since $\mathbf{M}(\infty) = \widetilde{\mathbf{M}}(\infty) = \mathbf{I}$, we deduce that

$$\mathbf{I} = \widetilde{\mathbf{M}}^{\mathsf{T}}\mathbf{M}. \tag{9.4}$$

In particular, it follows from (3.5) that

$$\left\{\begin{array}{lcl} \boldsymbol{M}(z) & = & (z\mp 1/\sqrt{2})^{-1/3}\boldsymbol{M}_\pm + \mathcal{O}(1), \\ \widetilde{\boldsymbol{M}}^{\mathsf{T}}(z) & = & (z\mp 1/\sqrt{2})^{-1/3}\widetilde{\boldsymbol{M}}^{\mathsf{T}}_\pm + \mathcal{O}(1), \end{array}\right. \quad \text{as} \quad z\to\pm 1/\sqrt{2}, \tag{9.5}$$

for some constant matrices $\boldsymbol{M}_\pm$ and $\widetilde{\boldsymbol{M}}^{\mathsf{T}}_\pm$. Then it follows immediately from (9.4) that

$$\widetilde{\boldsymbol{M}}^{\mathsf{T}}_\pm \boldsymbol{M}_\pm = 0. \tag{9.6}$$

9.4 *Local Parametrices*

Again, we need to solve RHP-**Z** locally, this time around ± 1, $\pm 1/\sqrt{2}$, and ∞. The local problems RHP-$\boldsymbol{P}_{\pm 1}$ are exactly the same as in Case I and therefore their solutions are given by (8.12)–(8.14).

9.4.1 RHP-$\boldsymbol{P}_\infty$

Let $R>0$ be large enough so that $\Delta_{02}\subset\big\{|z|<R\big\}$. In this section, we are looking for a solution to the following Riemann-Hilbert problem (RHP-$\boldsymbol{P}_\infty$):

(a) $\boldsymbol{P}_\infty$ is holomorphic in $\{|z|>R\}\setminus\Delta_{01}$ and

$$\lim_{z\to\infty,\pm\mathrm{Re}(z)>0} \boldsymbol{C}^{-n}\boldsymbol{P}_\infty(z)\mathrm{diag}\left(z^{-2n},z^n,z^n\right) = \boldsymbol{G}_1(\mp\rho/2);$$

(b) $\boldsymbol{P}_\infty$ has continuous traces on each side of $\Delta_{01}\cap\{|z|>R\}$ that satisfy $\boldsymbol{P}_{\infty+} = \boldsymbol{P}_{\infty-}\boldsymbol{G}_1(\rho_1/\rho_2)$;

(c) $\boldsymbol{P}_\infty = \boldsymbol{M}\left(\boldsymbol{I}+\mathcal{O}(n^{-1/2})\right)\boldsymbol{D}^n$ uniformly on $\{|z|=R\}$.

Let us show that RHP-$\boldsymbol{P}_\infty$ is solved by

$$\boldsymbol{P}_\infty := \boldsymbol{M}\boldsymbol{G}_1\left((\rho_1/\rho_2)(C_2/C_1)^n u\big(\sqrt{n/2}\zeta\big)\right)\boldsymbol{D}^n, \tag{9.7}$$

where the constants C_k are defined in (2.13), the function u is given by

$$u(\zeta) := \frac{1}{2}e^{2\zeta^2}\left\{\begin{array}{ll} \mathrm{erfc}\big(-\sqrt{2}\zeta\big), & \mathrm{Re}(\zeta)<0, \\ -\mathrm{erfc}\big(\sqrt{2}\zeta\big), & \mathrm{Re}(\zeta)>0, \end{array}\right.$$

and ζ is defined by

$$\zeta(z) := i\sqrt{\log\left(\Phi^{(1)}(z)C_2/\Phi^{(2)}(z)C_1\right)}, \quad |z|>R.$$

Indeed, $\zeta(z)$ is a conformal function in $\{|z|>R\}$ that vanishes at infinity by (6.14) (make R larger if necessary). Here, we choose the branch of the square root so that $z\zeta(z)$ tends to $(12)^{-1/4}$ when $z\to\infty$. Hence, we can deform Δ_{01} in $\{|z|>R\}$ so that $\zeta(\Delta_{01})\subset i\mathbb{R}$. Thus, the right-hand side of (9.7) is holomorphic in $\{|z|>R\}\setminus\Delta_{01}$. As it follows from [16, Eq. (7.2.2)] that

$$\lim_{z\to 0,\pm\mathrm{Re}(\zeta)>0} u(\zeta) = \mp 1/2,$$

RHP-$\boldsymbol{P}_\infty$(a) is indeed satisfied. To verify RHP-$\boldsymbol{P}_\infty$(b), notice that $\boldsymbol{G}_1(f_+) = \boldsymbol{G}_1(f_-)\boldsymbol{G}_1(f_+-f_-)$ and that $u_+(x)-u_-(x) = e^{2x^2}$ for $x\in i\mathbb{R}$. Since

$$\exp\left\{2(n/2)\zeta^2(z)\right\} = \left(\Phi^{(2)}(z)C_1/\Phi^{(1)}(z)C_2\right)^n$$

RHP-$\boldsymbol{P}_\infty$(b) follows. Finally, [16, Eq. (7.12.1)] implies that

$$u(\zeta)\sim\frac{1}{\sqrt{2\pi}}\sum_{k=0}^\infty(-1)^{k+1}\frac{\Gamma(k+1/2)}{2^{k+1}\Gamma(1/2)}\zeta^{-(2k+1)}$$

uniformly in the left and right half-planes. Hence,

$$\boldsymbol{P}_\infty = \boldsymbol{M}\left(\boldsymbol{I}+(\rho_1/\rho_2)(C_2/C_1)^n\mathcal{O}(1/\sqrt{n})\boldsymbol{E}_{3,2}\right)\boldsymbol{D}^n$$

uniformly on $|z| = R$. As $|C_1| = |C_2|$ by Theorem 3, we see that RHP-$\mathbf{P}_\infty$(c) holds as well.

9.4.2 RHP-$\mathbf{P}_{\pm 1/\sqrt{2}}$

Denote by $U_{\pm 1/\sqrt{2}} := \left\{z : \left|z \mp 1/\sqrt{2}\right| < n^{-1/2}\right\}$. In this section, we construct a solution to the following Riemann-Hilbert problem:

(a) $\mathbf{P}_{\pm 1/\sqrt{2}}$ is analytic in $U_{\pm 1/\sqrt{2}} \setminus \Sigma_{\mathbf{Z}}$;
(b) $\mathbf{P}_{\pm 1/\sqrt{2}}$ has continuous traces on each side of $\Sigma^\circ_{\mathbf{Z}} \cap U_{\pm 1/\sqrt{2}}$ that satisfy RHP-$\mathbf{Z}$(b);
(c) $\mathbf{P}_{\pm 1/\sqrt{2}}$ has the behavior near $\pm 1/\sqrt{2}$ within $U_{\pm 1/\sqrt{2}}$ described by RHP-$\mathbf{Z}$(c);
(d) $\mathbf{P}_{\pm 1/\sqrt{2}} = \left(\mathbf{I} + \mathcal{O}(n^{-1/6})\right) \mathbf{M}\mathbf{D}^n$ uniformly on $\partial U_{\pm 1/\sqrt{2}} \setminus \Sigma_{\mathbf{Z}}$.

In [15] (an alternative approach to asymptotics of multiple orthogonal polynomials around cubic branch point was developed in [36]), a 3×3 matrix function was constructed out of solutions to $zy'''(z) - \tau y'(z) + y(z) = 0$ that solves RHP-$\boldsymbol{\Upsilon}$:

(a) $\boldsymbol{\Upsilon}$ is holomorphic in $\mathbb{C} \setminus \left(L_+ \cup L_- \cup (-\infty, \infty)\right)$, where $L_\pm := \left\{\zeta : \mathsf{Re}(\zeta) = \pm \mathsf{Im}(\zeta)\right\}$ and the positive direction on all the lines goes from the left half-plane to the right half-plane;
(b) $\boldsymbol{\Upsilon}$ has continuous traces on $\left(L_+ \cup L_- \cup (-\infty, \infty)\right) \setminus \{0\}$ that satisfy

$$\boldsymbol{\Upsilon}_+ = \boldsymbol{\Upsilon}_- \begin{cases} T_2 \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} & \text{on} \quad L_\pm \cap \left\{\zeta : \mathsf{Re}(\zeta) > 0\right\}, \\ T_2 \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & \text{on} \quad (0, \infty), \end{cases}$$

and

$$\boldsymbol{\Upsilon}_+ = \boldsymbol{\Upsilon}_- \begin{cases} T_3 \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} & \text{on} \quad L_\pm \cap \left\{\zeta : \mathsf{Re}(\zeta) < 0\right\}, \\ T_3 \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & \text{on} \quad (-\infty, 0); \end{cases}$$

(c) $\boldsymbol{\Upsilon}(\zeta) = \mathcal{O}(\log|\zeta|)$ as $\zeta \to 0$;
(d) $\boldsymbol{\Upsilon}$ has the following behavior near ∞:

$$\boldsymbol{\Upsilon}(\zeta;\tau) = \mathbf{A}(\zeta;\tau)\left(\mathbf{I} + \boldsymbol{\Upsilon}_1(\tau)\zeta^{-1/3} + \mathcal{O}\left(\zeta^{-2/3}\right)\right)\exp\left\{-\frac{3}{2}\zeta^{2/3}\mathbf{B}^2 - \tau\zeta^{1/3}\mathbf{B}\right\}$$

uniformly for $\zeta \in \mathbb{C} \setminus \left(L_+ \cup L_- \cup (-\infty, \infty)\right)$ and τ on bounded sets with

$$\boldsymbol{\Upsilon}_1(\tau) = -\frac{\tau}{3}\left(\frac{\tau^2}{9} + 1\right)\mathbf{B}^2 - \frac{\tau}{9}\mathbf{C},$$

where

$$\mathbf{A}(\zeta;\tau) := \sqrt{\frac{2\pi}{3}} e^{\tau^2/6} T_2\left(\zeta^{\sigma_3/3}\right) \begin{cases} \begin{pmatrix} -e^{4\pi i/3} & 1 & e^{2\pi i/3} \\ 1 & -1 & -1 \\ -e^{2\pi i/3} & 1 & e^{4\pi i/3} \end{pmatrix}, & \mathsf{Im}(\zeta) > 0, \\ \begin{pmatrix} e^{2\pi i/3} & 1 & e^{4\pi i/3} \\ -1 & -1 & -1 \\ e^{4\pi i/3} & 1 & e^{2\pi i/3} \end{pmatrix}, & \mathsf{Im}(\zeta) < 0, \end{cases}$$

$$\mathbf{B} := \begin{cases} \mathsf{diag}\left(e^{4\pi i/3}, 1, e^{2\pi i/3}\right), & \mathsf{Im}(\zeta) > 0, \\ \mathsf{diag}\left(e^{2\pi i/3}, 1, e^{4\pi i/3}\right), & \mathsf{Im}(\zeta) < 0, \end{cases}$$

and

$$\mathbf{C} := \begin{cases} \begin{pmatrix} 0 & e^{4\pi i/3} - e^{2\pi i/3} & 1 - e^{2\pi i/3} \\ e^{4\pi i/3} - 1 & 0 & 1 - e^{2\pi i/3} \\ 1 - e^{4\pi i/3} & e^{4\pi i/3} - e^{2\pi i/3} & 0 \end{pmatrix}, & \mathrm{Im}(\zeta) > 0, \\ \begin{pmatrix} 0 & e^{4\pi i/3} - e^{2\pi i/3} & e^{4\pi i/3} - 1 \\ 1 - e^{2\pi i/3} & 0 & 1 - e^{4\pi i/3} \\ e^{2\pi i/3} - 1 & e^{2\pi i/3} - e^{4\pi i/3} & 0 \end{pmatrix} & \mathrm{Im}(\zeta) < 0. \end{cases}$$

Below, we explain how to solve RHP-$\mathbf{P}_{1/\sqrt{2}}$ using $\boldsymbol{\Upsilon}$, a solution of RHP-$\mathbf{P}_{-1/\sqrt{2}}$ can be constructed analogously.

To carry RHP-$\boldsymbol{\Upsilon}$ into a neighborhood of $1/\sqrt{2}$, define

$$\zeta(z) := \left(\frac{2}{3} \int_{1/\sqrt{2}}^{z} \left(x - \frac{1}{\sqrt{2}} \right)^{-1/3} \frac{H^{1/3}(x)}{\sqrt{1-x^2}} \, dx \right)^{3/2},$$

where the function H was introduced in (6.16) and we choose the principle branch of the square root. Then ζ is conformal in some neighborhood of $1/\sqrt{2}$, $\zeta(1/\sqrt{2}) = 0$, and $\zeta(x) > 0$, $x > 1/\sqrt{2}$. Further, define

$$\tau(z) := -\zeta^{-1/3}(z) \int_{1/\sqrt{2}}^{z} \left(x - \frac{1}{\sqrt{2}} \right)^{1/3} \frac{H^{-1/3}(x)}{\sqrt{1-x^2}} \, dx.$$

It readily follows that $\tau(z)$ is also conformal in some neighborhood of $1/\sqrt{2}$, $\tau(1/\sqrt{2}) = 0$, and that

$$\exp\left\{ -\frac{3}{2}\zeta^{2/3}(z)\mathbf{B}^2 - \tau(z)\zeta^{1/3}(z)\mathbf{B} \right\} = \mathbf{D}^n(z) \tag{9.8}$$

by (6.16) and (6.18), and since Φ has value 1 at the point of $\mathfrak{R}$ whose natural projection is $1/\sqrt{2}$. Set

$$\mathbf{E}_*(z) := \mathbf{M}(z)\mathrm{diag}\left(1, \rho_1^{-1}(z), \rho_2^{-1}(z)\right)\mathbf{A}^{-1}\left(n^{3/2}\zeta(z); n^{1/2}\tau(z)\right).$$

It can easily be verified that

$$\mathbf{A}_+ = \mathbf{A}_- \begin{cases} \mathbf{T}_2 \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & \text{on} \quad (0, \infty), \\ \mathbf{T}_3 \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} & \text{on} \quad (-\infty, 0). \end{cases}$$

As the entries of $\mathbf{M}$ as well as the entries of $\mathbf{A}^{-1}$ can have at most cubic root singularity at $1/\sqrt{2}$, the matrix $\mathbf{E}_*$ is holomorphic in $U_{1/\sqrt{2}}$. Then

$$\mathbf{P}_*(z) := \mathbf{E}_*(z)\boldsymbol{\Upsilon}\left(n^{3/2}\zeta(z); n^{1/2}\tau(z)\right)\mathrm{diag}\left(1, \rho_1(z), \rho_2(z)\right)$$

satisfies RHP-$\mathbf{P}_{1/\sqrt{2}}$(a–c) (we always can adjust $\Delta_{i\pm}$ so that ζ maps them into $\{\mathrm{Re}(z) = \pm\mathrm{Im}(z)\}$). It also follows from RHP-$\boldsymbol{\Upsilon}$(d) and (9.8) that

$$\mathbf{P}_*(z) = \mathbf{M}(z)\left(\mathbf{I} + \mathbf{F}_n(z) + \mathcal{O}\left(n^{-2/3}\right)\right)\mathbf{D}^n(z)$$

as $n \to \infty$ uniformly on $\partial U_{1/\sqrt{2}}$ (recall that $\tau(z)$ is conformal in $U_{1/\sqrt{2}}$ and vanishes at $1/\sqrt{2}$, which implies that $n^{1/2}\tau(z)$ remains bounded as $n \to \infty$ and therefore RHP-$\boldsymbol{\Upsilon}$(d) is applicable), where

$$\mathbf{F}_n(z) := n^{-1/2}\zeta^{-1/3}(z)\mathrm{diag}\left(1, \rho_1^{-1}(z), \rho_2^{-1}(z)\right)\boldsymbol{\Upsilon}_1\left(n^{1/2}\tau(z)\right)\mathrm{diag}\left(1, \rho_1(z), \rho_2(z)\right).$$

Since $\boldsymbol{\Upsilon}_1\left(n^{1/2}\tau(z)\right) \sim n^{1/2}\tau(z)$ as $z \to 1/\sqrt{2}$ or $n \to \infty$, we can write

$$(\mathbf{M}\mathbf{F}_n\mathbf{M}^{-1})(z) = \frac{\tau(z)\zeta^{-1/3}(z)}{(z - 1/\sqrt{2})^{2/3}} \left(\frac{4}{3}\mathbf{M}_+\mathbf{F}_n^*\widehat{\mathbf{M}}_+^T + \mathcal{O}\left(\left| z - 1/\sqrt{2} \right|^{1/3} \right) \right)$$

by (9.4) and (9.5), where $\mathbf{F}_n^*$ is a matrix of constants (more precisely, it is one matrix of constants in $\{\mathsf{Im}(z) > 0\}$ and another one in $\{\mathsf{Im}(z) < 0\}$, see the definition of Υ_1) with entries whose moduli are uniformly bounded as $n \to \infty$. As the fraction in the above equality is holomorphic around $1/\sqrt{2}$ and has value $-3/4$ at $1/\sqrt{2}$, we get that

$$(\mathbf{M}\mathbf{F}_n\mathbf{M}^{-1})(z) = -\mathbf{M}_+\mathbf{F}_n^*\widehat{\mathbf{M}}_+^{\mathsf{T}} + \mathcal{O}\left(\left|z-1/\sqrt{2}\right|^{1/3}\right).$$

Since $\left|z-1/\sqrt{2}\right| = n^{-1/2}$ on $\partial U_{1/\sqrt{2}}$, we have that

$$\mathbf{P}_*(z) = \left(\mathbf{I} - \mathbf{M}_+\mathbf{F}_n^*\widehat{\mathbf{M}}_+^{\mathsf{T}} + \mathcal{O}(n^{-1/6})\right)\mathbf{M}(z)\mathbf{D}^n(z)$$

uniformly on $\partial U_{1/\sqrt{2}}$. Thus, according to (9.6), RHP-$\mathbf{P}_{1/\sqrt{2}}$ is solved by

$$\mathbf{P}_{1/\sqrt{2}}(z) := \left(\mathbf{I} + \mathbf{M}_+\mathbf{F}_n^*\widehat{\mathbf{M}}_+^{\mathsf{T}}\right)\mathbf{P}_*(z).$$

9.5 *Final R-H Problem*

The final Riemann-Hilbert problem is RHP-$\mathbf{R}$ from Section 8.5 with $\mathbf{J}_Z$ defined in (9.3). The same analysis shows that the jump matrices in RHP-$\mathbf{R}$ are of order $\mathcal{O}(n^{-1/6})$ for $\mathbb{N}_* \ni n \to \infty$ and therefore RHP-$\mathbf{R}$ is solvable for all $n \in \mathbb{N}_*$ large enough and satisfies (8.25) with n^{-1} replaced by $n^{-1/6}$.

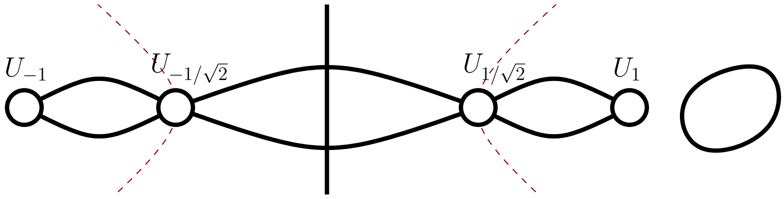

FIGURE 16. The contour $\Sigma_{\mathbf{R}}$ without the circle $\{|z| = R\}$ (solid lines) and the borders of the domains Ω_{ijk} (dashed lines), see Figure 3(b).

9.6 *Asymptotics of Hermite-Padé Approximants*

It can readily be verified that formulae (8.26), (8.27), and (8.28) remain valid. Let $\mathbf{R}$ be the solution of RHP-$\mathbf{R}$. Then the solution of RHP-$\mathbf{Z}$ is given by (8.29), where $e \in \{\pm 1, \pm 1/\sqrt{2}, \infty\}$, for all $n \in \mathbb{N}_*$ large enough. The same argument as before shows that (8.34) holds in this case as well.

Since the first column of $\mathbf{P}_\infty$ is the same as the first column of $\mathbf{M}\mathbf{D}^n$, (8.31) remains valid when $k = 0$. Thus, the proof of the first parts of (4.4) and (4.5) is exactly the same. The second parts of (4.4) and (4.5) are claimed to hold uniformly on each compact subset of the respective domains (because Γ_i contains the point at infinity and $\mathcal{N}_\delta^{(i)}$ is bounded). Hence, given a compact subset, we always can enlarge R in RHP-$\mathbf{P}_\infty$ so that this set is contained in $\{|z| < R\}$. This way (8.31) is valid on this compact and the remaining part of the proof is the same as in Case I.

10 RIEMANN-HILBERT ANALYSIS: CASE III

10.1 *Global Lenses*

Let $\mathbf{G}_1(u)$ and $\mathbf{G}_2(v)$ be as in (8.1). Fix a domain, say O_1, that contains $[-1,-b]$ and whose boundary $\Delta_{01} := \partial O_1$ is smooth, lies entirely in Ω_{012} (except for the point where it crosses $(-b, b)$), see Figure 3(c), while crossing the real line at the origin, see Figure 17. In Case

IIIa, denote by Δ_{02} a smooth Jordan curve lying within the right component of Ω_{021} and containing within its interior all the singularities of ρ_2/ρ_1 (recall that $\rho_2/\rho_1 \equiv \mathrm{const}$ in Case IIIb by Condition 8), see Figure 17. We also denote by O_2 the intersection of the exterior domains of Δ_{01} and Δ_{02}. We orient Δ_{01} and Δ_{02} counter-clockwise and set

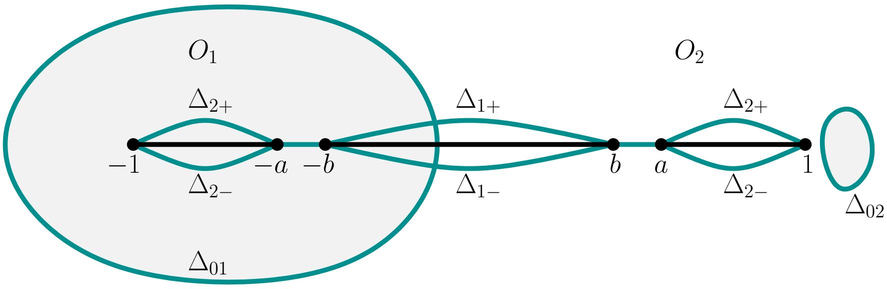

FIGURE 17. The lens $\Sigma_{\boldsymbol{Z}}$, the domains O_1 (shaded region on the left) and O_1 (unshaded unbounded region), local lenses $\Delta_{1\pm}$ and $\Delta_{2\pm}$. The curve Δ_{02} is present only in Case IIIa.

$$\boldsymbol{S} := \boldsymbol{G}_2\big((\rho_2/\rho_1)(\infty)\big)\boldsymbol{Y}\begin{cases} \boldsymbol{G}_2(-\rho_2/\rho_1)\boldsymbol{G}_1(\rho_1/\rho_2) & \text{in} \quad O_1, \\ \boldsymbol{G}_2(-\rho_2/\rho_1) & \text{in} \quad O_2, \\ \boldsymbol{I} & \text{in} \quad \overline{\mathbb{C}}\setminus\overline{(O_1\cup O_2)}\,. \end{cases} \tag{10.1}$$

Put $\Sigma_{\boldsymbol{S}} := [-1,1]\cup\Delta_{01}\cup\Delta_{02}$. Then, according to (8.2), $\boldsymbol{S}$ solves RHP-$\boldsymbol{S}$:

(a) $\boldsymbol{S}$ is analytic in $\mathbb{C}\setminus\Sigma_{\boldsymbol{S}}$ and $\lim_{z\to\infty}\boldsymbol{S}(z)\mathrm{diag}\left(z^{-2n},z^n,z^n\right) = \boldsymbol{I}$;

(b) $\boldsymbol{S}$ has continuous traces on $\Sigma_{\boldsymbol{S}}^\circ := \Sigma_{\boldsymbol{S}}\setminus\{\pm1,\pm a,0\}$ that satisfy

$$\boldsymbol{S}_+ = \boldsymbol{S}_-\begin{cases} \boldsymbol{J}(\rho_1,0) & \text{on} \quad \Delta_1^\circ\setminus\{0\}, \\ \boldsymbol{J}(0,\rho_2^*) & \text{on} \quad \Delta_2^\circ, \\ \boldsymbol{G}_1(\rho_1/\rho_2) & \text{on} \quad \Delta_{01}, \\ \boldsymbol{G}_2(\rho_2/\rho_1) & \text{on} \quad \Delta_{02}, \end{cases}$$

where ρ_2^* is defined by (8.4) and Δ_i in (2.8);

(c) $\boldsymbol{S}$ satisfies RHP-$\boldsymbol{Y}$(c) (see Section 5) with $[-1,1]$ replaced by $\Sigma_{\boldsymbol{S}}$.

If RHP-$\boldsymbol{S}$ is solvable, then so is RHP-$\boldsymbol{Y}$, and the solutions are connected via (10.1).

10.2 *Local Lenses*

As usual, we introduce additional arcs $\Delta_{1\pm}$ and systems of two arcs $\Delta_{2\pm}$ as in Figure 17, all oriented from left to right. We further denote by $O_{i\pm}$ the open sets bounded by Δ_i and the arcs $\Delta_{i\pm}$, $i\in\{1,2\}$. Set

$$\boldsymbol{Z} := \boldsymbol{S}\boldsymbol{L}_i^{\mp1} \quad \text{in} \quad O_{i\pm}, \tag{10.2}$$

where the matrices $\boldsymbol{L}_i$ are defined by (8.6). Put $\Sigma_{\boldsymbol{Z}} := \Sigma_{\boldsymbol{S}}\cup\Delta_{1+}\cup\Delta_{1-}\cup\Delta_{2+}\cup\Delta_{2-}$. Then it can readily be checked that $\boldsymbol{Z}$ solves RHP-$\boldsymbol{Z}$:

(a) $\boldsymbol{Z}$ is analytic in $\mathbb{C}\setminus\Sigma_{\boldsymbol{Z}}$ and $\lim_{z\to\infty}\boldsymbol{Z}(z)\mathrm{diag}\left(z^{2n},z^{-n},z^{-n}\right) = \boldsymbol{I}$;

(b) $\boldsymbol{Z}$ has continuous traces on each side of $\Sigma_{\boldsymbol{Z}}^\circ := \Sigma_{\boldsymbol{Z}}\setminus\{\pm1,\pm a,\pm b,0\}$ that satisfy

$$\boldsymbol{Z}_+ = \boldsymbol{Z}_-\begin{cases} \boldsymbol{J}_i & \text{on} \quad \Delta_i^\circ\setminus\{0\}, \quad i\in\{1,2\}, \\ \boldsymbol{J}_{\boldsymbol{Z}} & \text{on} \quad \Sigma_{\boldsymbol{Z}}^\circ\setminus(\Delta_1\cup\Delta_2), \end{cases}$$

where $\mathbf{J}_i$ are defined by (8.7) and

$$\mathbf{J}_\mathbf{Z} := \begin{cases} \mathbf{J}(\rho_1, 0) & \text{on} \quad (-a,-b)\cup(b,a), \\ \mathbf{G}_1(\rho_1/\rho_2) & \text{on} \quad \Delta_{01}, \\ \mathbf{G}_2(\rho_2/\rho_1) & \text{on} \quad \Delta_{02}, \\ \mathbf{L}_i & \text{on} \quad \Delta_{i\pm}, \quad i\in\{1,2\}; \end{cases} \tag{10.3}$$

(c) $\mathbf{Z}$ satisfies RHP-$\mathbf{S}$(c) with $\Sigma_\mathbf{S}$ replaced by $\Sigma_\mathbf{Z}$.

As before, if RHP-$\mathbf{Z}$ is solvable, then so is RHP-$\mathbf{S}$, and the solutions are connected via (10.2).

10.3 *Global Parametrix*

Let $\mathbf{N} = \mathbf{C}^{-n}\mathbf{M}\mathbf{D}^n$ be given by (8.9). Then $\det(\mathbf{N}) \equiv 1$ and it is a solution of the following Riemann-Hilbert problem (RHP-$\mathbf{N}$):

(a) $\mathbf{N}$ is analytic in $\mathbb{C}\setminus(\Delta_1\cup\Delta_2)$ and $\lim_{z\to\infty}\mathbf{N}(z)\mathrm{diag}\left(z^{-2n}, z^n, z^n\right) = \mathbf{I}$;
(b) $\mathbf{N}$ has continuous traces on each side of Δ_i° that satisfy $\mathbf{N}_+ = \mathbf{N}_-\mathbf{J}_i$, $i\in\{1,2\}$.

10.4 *Local Parametrices*

Again, as in the previous cases, we need to solve RHP-$\mathbf{P}_e$ for $e\in\{\pm1,\pm a,\pm b\}$. In fact, these local problems are exactly the same as in Case I. Thus, their solutions were constructed in Section 8.4.

10.5 *Final R-H Problem*

Once more, the final Riemann-Hilbert problem is RHP-$\mathbf{R}$ from Section 8.5 with $\mathbf{J}_\mathbf{Z}$ defined in (10.3) and $e\in\{\pm a,\pm b,\pm1\}$. Exactly the same analysis shows that the jump matrices in RHP-$\mathbf{R}$ are of order $\mathcal{O}(1/n)$ for $n\in\mathbb{N}_*$ and therefore RHP-$\mathbf{R}$ is solvable for all $n\in\mathbb{N}_*$ large enough and satisfies (8.25).

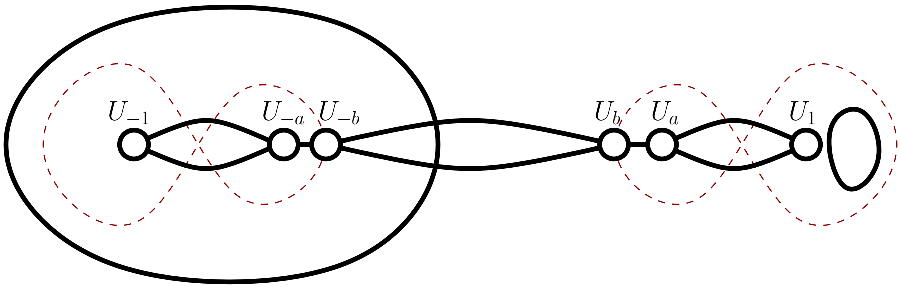

FIGURE 18. The contour $\Sigma_\mathbf{R}$ (solid lines) and the relevant borders of the domains Ω_{ijk} (dashed lines), see Figure 3(c,d).

10.6 *Asymptotics of Hermite-Padé Approximants*

As in Case I, one can verify that the formulae (8.26), (8.27), (8.28), (8.31), and (8.34) remain valid in this case as well. So the proof of (4.4) and (4.5) proceeds exactly along the same lines as in Case I.
